There has been throughout the year a very commendable diffusion of knowledge by sanitary conventions and journals, and through State Boards of Health, and perhaps some good has been effected through the laws that make hygiene, and especially the relation of alcoholics to disease, a part of our public school education, though it has often proved so small a part that it might have been eliminated without any appreciable change. Those who instruct must understand what they assume to teach before satisfactory results can obtain, and the public must comprehend the importance of physiology and hygiene before teachers will acquire the necessary knowledge. In America health, both public and private, has generally been left to take care of itself, and the scientists who devote their lives to its protection and development have too often been deemed impracticable cranks. Cure men of injuries and

on account of the unavoidable absence of its author.

diseases and they will at least load you with gratitude; save them from injury and disease, and your service is beneath consideration, and while governments have been disposed to pay and honor those rendering valuable service in other departments of life, too often neither pay nor honor has been awarded the sanitarium. Thus the first English army sent to the Crimea was decimated through want of sanitary care. With the second was sent a special sanitary commission, and after the campaign it returned in better sanitary condition than existed among the troops at home. The government crowned with honors the officers through whose neglect the first army was lost, but did not even commend those through whose wisdom the second was saved. Whilst this course has been the rule, during the year, Germany has made a commendable advance by conferring upon Koch a Baronetcy for distinguished service in the field of preventive medicine. In America, most of the States expect scientists to devote their lives to sanitation, on health boards and elsewhere, without fee or hope of reward, and to save the community from disease without adequate legal authority. Perhaps when sanitarians charge for their services they will be considered valuable, as mankind are disposed to estimate the value of every article at what it brings in the market. While practical sanitation is always a philanthropy it is never a charity. Scarce any other service yields so valuable a return. "An ounce of prevention is worth a pound of cure."

While in sanitary science many fields remain unexplored, and some differences exist, it is far in advance of its legally authorized application, and far enough advanced to see that the truth is within reach, and that few diseases are not amenable to its methods. If legal enactments for the preservation of health and life, were abreast with sanitary knowledge, the United States would annually save vast sums of money, thousands of years of productive labor and thousands of human lives. The recent advance in the department of medical education is full of encouragement. Since the organization of this Association, forty-four years ago, the burden of its prayer has been a *higher standard of medical education*. After twenty years of such effort, a committee, composed of its most eminent members, Drs. Gross, Bell, Condé, Pope and Bigelow, reported, "Its efforts have hitherto failed to produce any very great practical results;" and at the same meeting, another committee of equally distinguished physicians, Drs. Alfred, Stille and N. S. Davis, reported resolutions in favor of a better education as a pre-requisite to matriculation, and attendance upon three annual graded courses of medical instruction before admission to examination for a degree. During the past two decades the praying and resolving has gone steadily for-

ward, ably seconded by the American Academy of Medicine, yet, judging from a paper read before that body last year by Dr. Dunglison, these more than forty years of prayer have fallen short of the Throne.

The statistics of the past year are, however, very encouraging. According to the excellent report of that eminent sanitarian, Dr. John H. Rauch, in 1882, only forty-five colleges in the United States required any educational qualification for matriculation, now 129 require at least a good English education. In 1882, only twenty-two, and some of these relaxed, required three full courses of lectures of six months each: now there are eighty-five, one-fourth of them having been added, with others that have taken action since the publication of the report, during the past year. In 1882, only 52 colleges had a chair in State Medicine. In 1891, there is such a chair in 117 colleges. "Nothing succeeds like success." Nothing demonstrates the power of prayer like the demonstration. When we move forward toward the answer it comes with quickening power. Until then it remains

"The hidden motion of a fire
Within the human breast."

How much the action of the Illinois State Board of Health, requiring a three years' graded course as a pre-requisite to the acceptance of diplomas, and the results of the examining Boards of Virginia, North and South Carolina, Minnesota, New Jersey and Alabama had to do with hastening the answer, we will not stop to inquire, but I think we will all approve their action.

This advance, wherever honestly made, will tend to unify medical knowledge and destroy medical sects. "He who knows it half speaks much and is always wrong." Those who rest on their materia medicas, and antagonize the regular profession, which seeks to look at therapeutic action from every rational standpoint, though only as one to an hundred, are chiefly known by their clamor for equal representation on public boards, as though there could be a homeopathic hygiene, an eclectic etiology or a Christian science chemistry. Therapeutics is the roof that covers the temple; necessary to the temple, valueless without it. When the sciences from which spring both prevention and cure, are taught in graded courses, and absorb the thought of the physician, he will not thrust himself outside the pale of scientific medicine for such irrational dogmas as Ars., Bel., Bry., etc., cure whatever is set opposite them in the "Symptomatum Codex" of Hahnemann.

While the marvelous progress of this last quarter of the century has in many departments of life created contempt for the slower methods of education, in medicine, notwithstanding the tendency to the development of specialties, there has been an increased demand for good work.

thorough work, from all who cross its portals, both because there has been a truer conception of the length and breadth and depth of medical science, and a higher appreciation of the value of human life.

And we may well notice and commend the recent evidences among the people of increasing faith and interest in this department of medicine, manifested by such substantial methods as the gift of Henry C. Lea, of Philadelphia, the effort, with Mrs. President Harrison at its head, to endow a Medical Department at Johns Hopkins, and the kind words of Mrs. Gen. John A. Logan, in the *Home Journal*, in favor of endowing a medical department to the University about to be established at Washington.

As the broader possibilities of State Medicine become more and more demonstrable its relations to political economy and true statesmanship are more apparent.

It is unnecessary to recount before this Association the loss the nation sustains through preventable diseases, or the methods by which they may be prevented. While there may be errors in diagnosis, and while sanitary methods may not be infallible, it is the duty of the government to apply sanitary knowledge as fast as developed, and to develop sanitary science. If in its life destroying service it rightly says "Better that ten guilty men escape than that one innocent man perish," in its life saving service it may well say, better an hundred innocent detentions than that one infection laden person scatter yellow fever, cholera or small-pox, disease and death, throughout the land, especially now that quarantine has ceased to mean forty days and forty nights of fasting and prayer, but only disinfection and detention until the period of incubation has passed. If the citizen is entitled to protection against injury and death, accidental or designed, he is equally entitled to protection against the more numerous and dangerous foes, that he can neither foresee nor avoid, whose poisons enter his body with necessary air, water and food.

Every intelligent sanitarian and statesman understands the power of State Medicine to save from disease and death those for whom the State exists. Scarce two centuries have passed since small pox ravaged the earth in winter, and various plagues decimated it in summer. In London, then perhaps the most highly civilized city in the world, with a population of only half a million, during the winter months from one thousand to fifteen hundred per week perished from small-pox, taking its victims from among all classes. It robbed William the Conqueror of his beloved Queen and filled potters fields from the homes of the poor, and as the statesman and historian, Macaulay, has graphically said:

That disease over which science has since achieved a succession of glorious and beneficent victories was then

the most terrible of all the ministers of death. The havoc of the plague had been far more rapid, but the plague had visited our shores only twice within living memory; and the small-pox was always present, filling the churchyards with corpses, tormenting with constant fears all whom it had not stricken, leaving on those whose lives it spared the hideous traces of its power—turning the babe into a changeling at which the mother shuddered, and making the eyes and cheeks of the betrothed maiden objects of horror to the lover.

During the summer of different years from eight to ten thousand a week died of the plague, and when the city was not visited by special pests and plagues, the death-rate exceeded that of the modern London by more than forty per thousand, nearly twice the proportion that died last winter in Chicago. But this is not wholly a history of past ages. Wherever the same unsanitary conditions are permitted to obtain we still hear the tramp of the White Horse. Only two decades ago the yellow fever destroyed in our own Memphis an equally large proportion of lives.

The committee appointed by the Forty-seventh Congress to investigate and report the best means of preventing the introduction and spread of epidemic disease, reported:

In the yellow fever epidemic of 1878, which raged so fearfully and fatally at New Orleans, Memphis, Holly Springs and Grenada, and extended far up the Ohio River, and to many other places, the actual loss to the people of the United States in the element of material wealth, to say nothing of impaired health and loss of life, is variously estimated by those best informed on the subject, at from \$200,000,000 to \$200,000,000.

President Hayes, in his message to Congress, December, 1878, said:

It is impossible to estimate, with any approach to accuracy, the loss to the country occasioned by this epidemic. It is reckoned by hundreds of millions of dollars.

About one hundred thousand cases are believed to have occurred, of which about twenty thousand, according to intelligent estimates, proved fatal.

In a report made by the very efficient Secretary of the Michigan State Board of Health, Dr. Henry B. Baker, he says:

The annual saving of life has amounted to eleven hundred lives, representing seven thousand cases of sickness. Estimating each of these lives at only \$500 each, about half the value of an adult slave, and you have an annual saving of \$550,000. This the known saving from three diseases only.

Averaging the time that each of these seven thousand cases would have been unable to work at a fortnight, and there was an annual saving of 270 years of productive labor. Thus we begin to see the possibilities of State Medicine. If such results can obtain with crude and imperfect sanitary laws, hindered by State limitations, and in a State so illy appreciating these benefits that its Governor could formally recommend that the Board through whose efforts the results were obtained be abolished, what may we not hope as sanitary science and law develop, when the people appreciate their importance, and when the

National Government efficiently coöperates with the several States?

But what a comment on the intelligence of the people, when the Governor of a great State falls so far short of true statesmanship that he can recommend the abolishment of a Board that, through its most efficient Secretary, has produced such results.

Take one other illustration of what can be done, of what should be done, through State Medicine: Under the improved sanitary conditions of London in 1888, its deaths were 18.5 per 1,000. In the City of New York they were 25.9. Both in climate and location nature has done more for New York than for London, and its death-rate should be less. If, with the city of Brooklyn, in every way similarly situated, it was reduced to that of London, there would be an annual saving of 15,988 lives, and if two persons should be continuously sick for each one dying, there would, by reducing the sick-rate to that of London, be an annual saving of nearly 32,000 years, and if the expectation of these lives was counted, what innumerable years would be saved, to say nothing of the expense of this excessive sickness and death, or of its suffering and sorrow. If this in New York alone, what of the National loss that State Medicine, properly applied, would save? Is the statesman wise, is the legislator a statesman or a philanthropist who permits this preventable loss of life and labor?

One of America's greatest men has described this as a Government "of the people, by the people, for the people," a nation where all power emanates from the people, and where all power not delegated to the General Government remains with the States, the intent being to delegate all power that the individual States cannot efficiently exercise. We are a nation of nations, with the grandest conception of rights, and the broadest provision for their protection known to man, assuming that "all men are created equal," not physically, intellectually or morally, but equal before the law, possessing an equal right to exercise and enjoy every natural right, an equal right to "life, liberty and the pursuit of happiness." Life and all its possibilities first, for in its preservation lie all other rights, and in its development, physically, intellectually and morally, all the best interests of the individual and the State, and liberty, without which life has little value—not liberty to do wrong, for no one possesses a natural, or can acquire a political right to advance his own at another's expense; not liberty "to secure the greatest good to the greatest number," but liberty to attain the greatest possible good without injury to another.

This principle not only lies at the foundation of State Medicine, but of all good government.

At the organization of this Government various departments were created, all looking toward

the development and protection of its varied interests. While we concede the importance of all these and of those created through the development of other interests, we naturally inquire for whom do they, for whom does the State exist? Is the thing created superior to those for whom it was created? Is not the health, the development, the life of the people its highest interest? Surely the treasures about their hearth-stones, the lives of friends and neighbors, are more dear to the people than either commercial or financial interests, or "the cattle upon a thousand hills."

While all civilized nations have recognized the value of life, inflicting their severest punishment upon those who wantonly and maliciously destroy it, no adequate provision has ever been made for its protection against the causes by which it is constantly being destroyed. Is there not inconsistency in laws that destroy the life of him who wantonly destroys the life of another, while for each life thus destroyed they permit the destruction of an hundred or a thousand by preventable disease. If life is the highest interest of the nation, the dearest right of the citizen, the nation that fails to make every possible provision for its protection is inexcusable. Is a life taken by the stiletto or the bullet a greater loss to the nation, to the individual or to his friends, than when destroyed by pestilence or plague?

The National Government has recognized from its organization its authority and power to control disease, but lack of sanitary knowledge on the part of the legislator, whose education has not included sanitary science, has made medical legislation inefficient, while those selected to administer the law have too often been appointed for party purposes.

In February, 1776, Congress authorized the President to assist the States in preventing the admission of disease from foreign countries. Three years later the authority was extended and placed under the control of the Treasury Department, not, it would seem, from any just appreciation of the importance of saving life, or from any natural relation between health and finance, but because quarantines interfere with commerce, and commerce was a source of revenue, and so revenue has ever been deemed better than health by the legislator.

In 1798, the Marine-Hospital Service was organized, its purpose being to make provision for a class of citizens who served the nation on the high seas, but who were homeless when at home. For the same reason this too was placed under the care of the Treasury.

With a few unimportant provisions the status of State Medicine remained unchanged for more than half a century. After Asiatic cholera had thrice visited our shores, carrying death wherever it went, and after civil war had more fully demonstrated the relations of medicine to public health,

Congress authorized the Secretary of the Treasury to adopt such measures as would guard the nation against another invasion of cholera, and placed at its disposal an ample fund for the purpose, but, as if doubting the power or the wisdom of preventive measures, it only provided for its expenditure during the seven months intervening between May 26, 1866, and January 1, 1867. Though the hastily and imperfectly organized measures did not keep the disease from the country, they robbed the destroyer of his accustomed victories, and illustrated the possibilities of State Medicine.

Ten years later Congress authorized the application of preventive medicine to the District of Columbia, and this beautiful city was lifted out of the mud and transformed from one of the most unsanitary to one of the most healthy cities in the world.

Stimulated by the ravages of yellow fever, in 1878 Congress provided for a Health Commissioner for the District, and a health officer at a salary of \$3,000, and the same year an Act was passed requiring the Surgeon-General of the Marine-Hospital Service to make rules for certificates by foreign consuls, showing the condition of vessels and cargoes bound for the United States.

Hitherto all action looking to the application of State Medicine had been indirect, both National and State Legislatures fearing, apparently, to acknowledge its power.

In 1879 Acts were passed creating a National State Board of Health, defining its powers, and authorizing it to prevent the introduction of contagious and infectious diseases, its most important feature being the acknowledgment of State Medicine as a *life-saving service*. Hitherto it had been a "penny wise" affair, placed under the Treasury and created to save money. The National Board of Health was a political acknowledgment of the value of human life, and was required to report directly to the President of the United States. Though, like many of the State Boards, which were the prophets of its birth, it was created under a pressure that convicted without convincing the legislator, many of its provisions were crude and imperfect. With the battle on, it was thrown into action with the information and order of General —: "There is good fighting all along the line. Go in anywhere," but it achieved a success that will make it memorable in the history of State Medicine. Working in harmony with local boards of health, it strengthened their arms, and carried hope to their people, and changed the plague-stricken Memphis from a lazaretto to one of the healthiest cities of the South. In addition to illustrating the control of sanitary science over the great American plague, it published many valuable scientific papers and demonstrated the possibilities of preventive medicine.

While great credit is due to all connected with

it, its powers were too limited and ill-defined and it lacked the single and forceful head, as essential in our conflict with the hidden foe that is ambushed in the dark lanes and alleys of our cities, and in every swamp and bayou, as against an army with banners. While legislation in the interest of health has often been liberal when some great plague has struck terror to all hearts, efforts at such times are like attempts to stay the floods of the Father of Waters when the levees have broken; or to fortify a city with the enemy in its streets. To insure success provision must antedate invasion. There must be permanent authority with power to act, to insure protection against zymotic disease.

The Marine-Hospital Service, with an executive head clothed with the energy of Surgeon-General Hamilton, has still further illustrated the vital importance to the nation of State Medicine. But this Service was organized for a narrow sphere of duty, and though its boundaries have been greatly enlarged, its authority comes second-hand from a department with which preventive medicine has nothing in common, save that "public health is public wealth." It is only an indirect National acknowledgment of the possibility of staying the ravages of disease.

Boards of Health have been organized in nearly every State in the Union, and wherever they have been composed of scientific sanitarians, and lifted above the narrow lines of party politics, and given authority to act, they have been active factors in the development of State Medicine. But the plagues that destroy recognize no State lines, know no State rights, and when the several States delegated to Congress the right to regulate commerce with foreign nations, and among the States, they planted better than they knew, and gave the National Legislature authority to exclude from the country the great plagues that follow commerce, and to interdict their passage from State to State; but if the Supreme Court has decided correctly, that a State has no right to prevent alcoholic liquors from crossing State lines, and being distributed in original packages, a State has no right to prevent original packages containing the germs of septic disease from being admitted and distributed among the people. To secure the full force of State Medicine there must be a National head with power to coöperate with State and local boards of health.

The constitution has also wisely provided that Congress shall have power to provide for the common defense and general welfare of the United States. Does not the general welfare include defense against the preventable diseases that cause more suffering and death than all other causes—diseases that "walk in darkness and waste at noonday," against whose poisoned arrows the citizen, in his individual capacity, is powerless to secure protection.

The National Government, through its various departments, collects accurate statistics demonstrating the condition of commerce, manufactures, agriculture, mines, all that has hitherto been considered the important factors of political economy, but it has never realized that vital statistics are its only means of measuring the life wave of the nation, of keeping the life account, on which rests all its political economy, and the only foundation of sanitary science. Without knowing where disease exists, its disabilities and deaths, its causes and means of prevention, there is no possibility of knowing when, where, or how to prevent or arrest it.

That eminent scientist and sanitarian, Surgeon Billings, with most commendable zeal and great labor has endeavored to evolve out of the imperfect data furnished, the vital statistics of the nation, but the result has necessarily been imperfect and unsatisfactory.

Mind and morals act through matter. To evolve healthy mental and moral action there must be healthy physical organisms. The children of the nation spend a long portion of the formative period of their lives in its schools. Its health interests demand their scientific sanitary supervision.

The National Government should also decide who may enter its life-saving service. It requires the attainment of a certain standard or qualification to those who enter this service in the Army and Navy and Marine-Hospital. Are those who serve it in these departments any more important members of the body politic than the citizen who develops the industries of the nation, pays its expenses, makes and unmakes its officers? It may be said that they pay for the services they receive, and are capable of judging of the qualifications of those they employ. In this busy world few men acquire the knowledge that will enable them to judge of the qualification of a medical adviser. The general welfare of the United States demands that the government establish a standard of medical education which shall be attained by those who enter its life-saving service, that every citizen may know when his life is broken by disease or injury, that the government only permits those worthy and well qualified to administer to his wants. The fact that the citizen pays for the service does not exonerate the State from providing that he shall receive that for which he pays, and that its protection shall operate wherever its flag may float.

The medical college is responsible for medical education. While great honor is due to the distinguished men who, without State or National aid, have built up their medical schools, advanced the standard of medical education and performed the most important educational service known to the nation, the preparation of those who have charge of the life and health of the people, they

have too often been compelled to snatch their lecture hours from an exacting and poorly paid practice, and to lecture without the aid of the original investigation and research essential to true progress; and unfortunately, in many States, any half dozen citizens can secure a charter for a medical school and graduate whomsoever they will. Does not "the general welfare" demand that the National Government shall establish a standard of qualification, and that the State shall provide such aid to this important branch of education as will enable teachers to devote themselves to its interests?

Government is as much bound to protect the citizen against ignorant pretenders in medicine as against preventable disease, and as much bound to extend protection against disease as against death from any other cause. This can only be done through provision for original research in the investigation of disease.

While progress in preventive medicine has been slow, perhaps because of the work of medical philanthropists, who in preventing disease have limited the income of a profession that lives by curing disease, have done the work for nothing, gone afoot and paid their own fare, the progress has been sufficient to demonstrate the importance of a National department that will not only utilize the knowledge already acquired, but prosecute such further investigations as will secure richer blessings.

The enlightened statesman knows that the strength of a nation lies in the strength of its people, and that the highest function of law is the protection of their life, health and development, that "public health is public wealth." When he comprehends that the great epidemics that destroy mankind, causing untold suffering and immeasurable financial loss, are amenable to State Medicine, may we not believe that the National Government will establish *A Department of Public Health*, under whose protecting aegis it will gather the Marine-Hospital Service, the Bureau of Education, of Vital Statistics and of Animal Diseases, the Climatological and Signal Service, all that pertains to the health and development of the people, providing that, as in the Army and Navy, its appointments shall be preceded by thorough examination and made for life. In such a department there would be enrolled a body of scientists unequalled in the world, working in harmony for the highest interests of mankind—the prevention of disease, the preservation of life and the uplifting of humanity, giving dignity to State Medicine and the highest possible physical, intellectual and moral development to the nation. The most hopeful event during the past year is that a bill looking to this end was introduced into Congress. Such a department devoted to original research and lifted above political mutations, guided by the

energy and intelligence of a Hamilton, a Rauch or an Eaton, will be an honor to the nation and a blessing to the world, and will hasten the day when preventive medicine and surgery will well nigh cover the field of medicine, when health will be the rule and disease the rare exception, when "The days of man shall be three score years and ten and if by reason of strength four-score years," nay, five-score years, five times the length of his development period.

ORIGINAL ARTICLES.

THE GROWING IMPORTANCE OF CHEMICAL STUDIES IN MEDICAL EDUCATION AND IN MEDICAL RESEARCH.

Read in the Section of the Practice of Medicine and Physiology at the the Forty-sixth Annual Meeting of the American Medical Association, at Washington, D.C., May 5, 1894.

BY VICTOR C. VAUGHAN, M.D.,

OF ANN ARBOR, MICH.

Gentlemen of the Section:—The object which I have in view in the selection of this subject is to call your attention to the present importance of chemical studies in the elucidation of medical problems. Chemical theories and discoveries have frequently in the past been of service to medicine, but they offer much greater promises for the future. With the past services you are familiar, and I desire to point out some of the most important problems which are now being investigated or which only await careful study.

The Chemistry of the Animal Cell.—With the form and size of the various cells of the animal body, both in health and in disease, we are fairly acquainted, but we must remember that these ultimate entities of life have also a physiological and a chemical history. Their function, as well as their form, is deserving of study. Upon what do they feed? What is the nature of their secretions and excretions? These and many other questions pertaining to their life history are worthy of study.

The diverse ways in which the various cells of the body and the several parts of the same cell are affected by staining reagents suggest important differences in chemical composition. The work of Miescher¹ and Kossel² has given us much valuable information concerning the composition of the nucleus of the cell. They have shown that certain compounds exist as characteristic constituents of the nuclei. These belong to the proteids, but differ from other members of this group inas-

much as the albumin molecule is not free, but combined with phosphoric acid. This combination is exceedingly loose and can be broken up by boiling with water. In fact decomposition occurs at ordinary temperature if the compound is kept moist. This substance has been called by Miescher nuclein. It has been generally supposed that the phosphoric acid in the body exists as inorganic salts. This is true of the most of that contained in the bones, muscles and blood, but not of that of the glandular organs. Kossel has shown that from 60 to 75 per cent. of the total phosphoric acid in the spleen exists as nuclein, while from 30 to 50 per cent. of that of the liver, and 50 per cent. of that of the pancreas is found in the same combination. The smaller the proportion of nucleated cells in any tissue, the smaller is the amount of nuclein. In the muscle of the adult animal the amount of phosphoric acid in combination with albumin is only 7 per cent. of the total phosphoric acid.

It will be seen from the above that the amount of organically combined phosphoric acid is a measure of the nuclear substance in a given tissue, and this can be isolated and weighed, thus giving a more exact estimate than that obtained by counting the nuclei under a microscope. This procedure can be made serviceable not only in physiological but in pathological work. Thus, Kossel finds that while the amount of nuclein-phosphoric acid in normal blood is too small to admit of quantitative determination, as much as 51 per cent. of the total phosphoric acid in leucocythæmic blood may exist in this form. Again, in the examination of pus, the chemical method will detect degenerative changes in the corpuscles before they can be recognized by the microscopical examination of unstained specimens.

However, albumin and phosphoric acid are not the only constituents of the nuclei. Nuclein, on being artificially decomposed, furnishes certain basic substances, as adenine, guanine, hypoxanthine and xanthine, which are characterized by the large amount of nitrogen which they contain. Adenine contains no oxygen, is a polymer of hydrocyanic acid, and indicates by its reactions that it belongs to the cyanogen compounds. Schindler³ has shown that 7 per cent. of the total nitrogen of the thymus gland exists in adenine. The large amount of hypoxanthine and xanthine in leucocythæmic blood arises from the decomposition of the nuclein.

Nuclein seems to be an acid which in the various tissues is combined with a base of somewhat variable composition. This basic substance is called by Kossel, "histon," and it has been designated by Miescher as a "basic pepton."

The above mentioned facts throw much light upon phenomena which have long been observed, but not understood, by histologists. The marked

³ Berliner klin. Wochenschrift, 1889, S. 416.

tendency of the nuclei to act as reducing agents is explained by the presence of the oxygen-free molecule of adenine, and the molecules of guanine, hypoxanthine and xanthine, whose ready transformation into more highly oxidized products is well known. The action of acetic acid on nuclei is due in part to the precipitation of the nuclein, and in part to the fact that it dissolves out the basic substance.

These researches have also been of service in the study of the function of the nuclei. Kossel¹ has shown that after prolonged hunger the nuclein is not diminished. This substance does therefore not form a reserve food supply, as is the case with glycogen, fat, and in part with albumin. He has also demonstrated that the nuclein serves in some way yet unknown in the building up of tissue. The muscles of the young animal are rich in glycogen while those of the adult contain only traces. The fact that adenine belongs to the cyanogen group, already mentioned, is suggestive in this connection. Cyanogen bodies have a well known tendency to transform themselves into substances having a complicated constitution. Hydrocyanic acid changes, on standing, into a brown mass, known as azulmic acid, which has a complicated, and as yet unknown, chemical structure; and adenine undergoes, under certain conditions which obtain in the body, a similar transformation. This offers, at least, a suggestion as to the manner in which the animal cell accomplishes its synthetical work. The fact that adenine belongs to the cyanogen group is further suggestive in consideration of the formation of both the bacterial and metabolic poisons from proteids. Adenine itself, in quantities of one gram and slightly less, is fatal to dogs of medium size when administered by the mouth. No study of its effects when injected subcutaneously or intravenously has yet been made, so far as I know.

After a study of the facts, which I have briefly placed before you, one cannot avoid the impression that continued investigations in this line may lead to important discoveries which will be of service to us in unraveling the mysteries of cell activity. With the promise of such a reward the labor and energy of a lifetime may be given to this work. With a knowledge of the conditions under which cells multiply, of the nature of their pabulum, of the manner in which they convert foods into living tissue, what a great advantage the scientific physician of the future will have over us, his ignorant predecessors, who are yet compelled to rely so largely in the treatment of disease upon empiricism.

The intelligent chemist of to-day does not dream that by the aid of his science he will ever be able to construct a living cell, but he does hope to ascertain the conditions under which cells thrive and multiply, and those under which they

die. He may acquaint himself with the nature of their substance, and from this knowledge he may be able to supply them with proper food. He may point out to the practitioner the effects of certain therapeutic agents upon the cells of the liver and, what will be of equal importance, the action of the cells of the liver upon the therapeutic agents. We are at present wholly ignorant of the changes wrought by the chemistry of the body in the majority of the drugs which we employ. We know but little of the form in which our medicinal agents reach the diseased organ, and yet without any knowledge on this essential point we endeavor to effect the nutrition of the various parts of the body. A substance may undergo one or more marked changes in chemical composition during its passage through the body. Thus camphor $C_{10}H_{16}O$ is first converted into camphorol $C_{10}H_{15}OH$ by taking up hydroxyl, and finally is eliminated from the body in combination with glycuronic acid. Not only does the camphor undergo these changes, but evidently it alters tissue metabolism. Glycuronic acid $C_6H_{10}O_6$ is a product of beginning oxidation of sugar, and in normal tissue metabolism rapidly goes through other steps in the process of oxidation and breaks up into carbonic dioxide and water, but when brought in contact with a substance not readily oxidized, such as camphor, it is eliminated from the body unchanged. Changes in physiological action often follow from these alterations in chemical structure. A poison may be rendered inert, or an inert body may be converted into a poison. As an example of the former, the fact that a certain amount of the highly poisonous substance, phenol, is changed into phenol-sulphuric acid, which is inert, may be mentioned; while a change in the opposite direction occurs in those persons to whom a bit of egg or some article of common food is poisonous.

With some of the synthetical changes brought about by the living cell, the labors of physiological chemists have already made us familiar. The work of Bunge and Schmiedeberg² on the formation of hippuric acid might be taken as a model for similar investigations. That benzoic acid administered by the stomach appears in the urine in the form of hippuric acid was first observed by Wöhler in 1824. Historically this fact is of interest because it was the first demonstration of synthetical processes in the animal body, and was at variance with the then, and for many years thereafter, dominant theory of Liebig, who taught that all the chemical changes in the animal body are analytical. Bunge and Schmiedeberg instituted a series of experiments with the view of determining what cells of the body are concerned in the synthesis of hippuric acid. First, benzoic acid and glycocholl were injected into the dorsal

¹ Berliner Klin. Wochenschrift, 1888, 8, 225.

² Archiv. f. Experiment. Path. u. Pharm. B. 1, 3, 231.

lymph-sacs of frogs from which the liver had been removed. The appearance of hippuric acid in the urine demonstrated that the liver was not, at least, the only organ in the body which synthesizes hippuric acid. It was next shown that hippuric acid is not formed in nephrotomized dogs. From this, however, it could not be positively asserted that the synthesis occurs in the kidneys, for it might be said that the removal of the kidneys had so disturbed the other organs of the body that they did not perform their functions normally. But this criticism was seen and provided for by another experiment. It was found that the passage of defibrinated blood, to which benzoic acid and glycocholic acid had been added through a kidney after its removal from the body, was accompanied by the synthesis of hippuric acid. It was thus shown that the extirpated kidney is capable of carrying on this synthesis. This is found to be true even after the excised kidney has been kept in a refrigerator for forty-eight hours. Then the question arose, is this synthesis accomplished by the living cell of the kidney or by some lifeless chemical constituent of the organ? Further experiments showed that the synthesis does occur if blood containing benzoic acid and glycocholic acid is allowed to stand in contact with a kidney which has been cut into pieces, but does not occur if the pieces be rubbed up in a mortar with glass into a homogenous mass. From this it is concluded that the activity of the living cell is essential to the performance of this function. Furthermore, it has been demonstrated that the synthesis will not occur if blood, which has been freed from its corpuscles, is employed, and the same is true if blood in which oxygen has been displaced by carbonic oxide is used.

Equally valuable with the above are the investigations of Schröder,⁶ by which he has shown that urea is in part at least formed in the liver from ammonium carbonate, and the labors of Minkowski⁷ on the formation of uric acid. Both of these experimenters have, as you know, demonstrated facts which are of importance physiologically, and which have also cleared up some hitherto unexplained observations in pathological states.

It may not be out of place to point out the desirability of another investigation similar to those mentioned above. Physiological chemists are much impressed with the theory that kreatin is one of the antecedents of urea. However, if kreatin be administered by the mouth or injected into the blood it reappears in the urine, either unchanged or in the form of kreatinin. This is supposed by some to be sufficient proof that it is not an antecedent of urea, but, as Bunge⁸ states, this is not necessarily the case, because the kre-

atin formed in the muscles may in its nascent state be converted into urea, while the same substance injected into the blood may escape this transformation. This question is one of great practical importance, and its solution promises to throw some light upon so-called uræmia, the chemical causation of which has recently received some confirmation, although the old idea that the retained urea is the active poison, and the theory of Frereichs that ammonium carbonate is the harmful substance, have both been abandoned. Landois⁹ laid bare the surface of the brain and sprinkled the motor area with kreatin, kreatinin and other constituents of the urine. Urea, ammonium carbonate, sodium chloride and potassium chloride had but slight effect; but kreatin and kreatinin caused clonic convulsions on the opposite side of the body, which later became bilateral. These convulsions continued at intervals for from two to three days, when, growing gradually weaker, they disappeared. From this, Landois concludes that chorea gravidarum is a forerunner of eclampsia. Now, kreatin is chemically, as has been shown by Volhard¹⁰ and Strecker,¹¹ a substituted guanidin, and it only needs to be converted into methyl-guanidin in order to produce all the convulsive symptoms observed in so-called uræmia. Moreover, Brieger¹² has shown that certain bacterial cells are capable of transforming the inert kreatin into the powerful convulsive poison, methyl-guanidin. The probabilities are that the cells which under normal conditions convert kreatin into urea are so affected by the accumulation of their own product, urea, which the kidneys fail to properly eliminate, that one substituted guanidin, kreatin appears as another member of the same class, methyl-guanidin, the former being a physiological product and not harmful, while the latter results from a modified and abnormal action, and is highly poisonous. I will admit that this theory has much reason in it, and I am now pointing out some of the medical problems which demand chemical studies for their elucidation, and I would suggest that an examination of the muscles of the brain of one who has died from so-called uræmic convulsions for methyl-guanidin, and a determination of the amount of kreatin in the same organ, would be a work worthy of the time given to it, whatever the result may be.

The statements made above find important support in the recent highly valuable work of Drechsel,¹³ in which he has prepared lysatin and lysatinin directly from casein, and from these, urea. Lysatin and lysatinin are homologous with kreatin and kreatinin, and on being boiled with baryta will yield urea. Although we have long

known that the urea eliminated in the urine must have its origin in the proteids of the food, Dreschel is the first chemist who has been successful in breaking up a proteid by artificial means in such a way as to produce urea. The same is true of the formation of a kreatin from a proteid. This, which may be ranked as the most important of recent contributions to physiological chemistry, adds greatly to our knowledge of the kreatin bodies, and suggests a possible solution of the relation existing between these and urea in the normal metabolism of tissue. The physiological action of lysatin has not been as yet studied, nor is it known whether or not it would reappear in the urine as urea if given by the mouth or intravenously. We may sum up the positive knowledge which we have on this point as follows: 1. A number of substances belonging to the kreatin group are formed from proteids (some in the body, as kreatin, kreatinin, cruso-kreatinin, xantho-kreatinin and amphi-kreatin, and some by artificial means, as lysatin and lysatinin); 2. Kreatin is a substituted guanidin; 3. Methyl-guanidin is a highly poisonous substance, and this is true of both that obtained from putrefying flesh and that prepared from kreatin. It produces marked dyspnoea, muscular tremor and general clonic convulsions.

That there is a marked disturbance of tissue metabolism caused by the inhalation of vitiated air has been shown by Araki.¹¹ In the urine of animals rendered unconscious by being kept in a confined space this experimenter found albumin, sugar and lactic acid. If the animals had been kept without food for some days before being subjected to this experiment, albumin and lactic acid, were found, but no sugar appeared. This was undoubtedly due to the fact that the glycogen of the body had been exhausted by the fasting. Identical results were observed in animals, which were poisoned with carbon monoxide. Dogs which were poisoned with curare, and in which the respiratory movements were maintained artificially secreted very little urine, but the blood was found to contain considerable quantities of sugar and lactic acid. The urine of frogs in which the respiration was retarded by the production of tetanus with strychnia secreted urine containing sugar and lactic acid. In the urine of three epileptics there were found albumin and lactic acid directly after the seizure. The factor common to all these cases is diminished oxygenation of the blood, and to this is ascribed the appearance of the abnormal constituents of the urine. These investigations demonstrate the influence of impure air upon the chemistry of the living cells of the animal body.

The chemistry of the absorption of foods offers an interesting chapter in the study of the activity of the animal cell. As practitioners of

medicine we bestow much attention upon the subject of digestion. We administer acids and digestive ferments, often without effect. The manufacturing chemists flood the market with preparations of pepsin and pancreatine, with their so called malted and digested foods, and I fear that we too often are deluded with the idea that it is only necessary to supply our patients with these ferments or foods in order to build up a worn-out body and restore strength to weak muscles and exhausted nerves. There is a popular—I fear that I might without any exaggeration say a professional idea—that peptones filter through the walls of the intestines without let or hindrance, and pour their treasures of strength and energy into the blood-vessels. However, scientific experiments have shown that this is altogether erroneous. In the first place albumin may be absorbed without having been previously converted into peptone. Voit and Bauer¹² washed out loops of the small intestines in living dogs and cats, ligated both ends of the loop, injected into the loop albuminous solutions, replaced the intestine within the body, and after from one to four hours determined the amount of albumin remaining in the loop. It was found that the amount absorbed during this time was, for egg-albumin from 16 to 33 per cent., and for acid albumin from muscles, from 28 to 95 per cent. Voit and Bauer think that they proved that there was no active digestive ferment in these loops by demonstrating that the portion unabsorbed contained no peptone.

The experiments of Eichhorst¹³ have led him to the same conclusion, but the most positive evidence which we have on this point has been furnished by the investigations of Czerny and Latschenberger.¹⁴ In a case of preternatural anus at the sigmoid flexure, it was found that albuminous solutions injected into the thoroughly washed piece of intestine below the fistula was absorbed after from twenty-three to twenty-nine hours to the extent of from 60 to 70 per cent. Without citing further experimental evidence upon this point it is sufficient to say that it has been conclusively shown that albumins may be, and often are, absorbed to a marked extent, without previous conversion into peptone. It should be understood that I do not claim that egg-albumin is ordinarily absorbed unchanged, but as Prior¹⁵ has shown even this may occur when excessively large amounts of egg-albumin are taken in the food. (In such a case the albumin is not apparently utilized by the tissue, but acting as a foreign body, it is eliminated in the urine.) But there are many reasons for believing that in health a small part of our proteid food is never converted into peptones but is fitted for its

service to the animal economy during its absorption through the walls of the intestines. The active agents which render this portion fit to enter the circulating blood are not the unorganized, digestive ferments, but are the living cells of the absorbing mechanism.

There are some good arguments in favor of the theory that all the proteid which is utilized in building or repairing tissue escapes conversion into peptones in the alimentary canal, and that proteids which have been converted into peptone can serve only as a source of energy, but cannot be utilized by the animal cell in the reconstruction of wasted muscles. If the defibrinated blood of one dog be injected directly into the veins of another the amount of urea eliminated by the latter is not materially increased, but if the defibrinated blood be administered by the stomach the increased amount of urea is large and in exact proportion to the quantity of the proteids in the blood administered.

A still more important fact is the demonstration that peptone is converted into serum albumin during absorption. Should the peptones reach the circulation unchanged they act as poisonous bodies. Injected into the blood they are soon eliminated unless the quantity is sufficiently large to cause marked toxic effects. The conversion of peptone into albumin by the mucosa of the walls of the alimentary canal has been beautifully shown by Salvioli working under the direction of the veteran physiologist, Ludwig. A loop of the intestine with the attached mesentery was taken from a dog. In the piece of the intestine there was placed one gram of dissolved peptone. Then the collateral branches having been ligated, a stream of defibrinated blood diluted with salt solution was caused to flow for four hours through the attached branch of the mesenteric artery. During this time the fact that the cells of the intestine retained their vitality was shown by the active contractions of the piece. At the expiration of the given time there was no peptone either in the intestine or in the blood. A further experiment showed that peptone added to the injected blood did not disappear. Consequently the only conclusion which is warranted by the facts is that the peptone is converted into albumin during its passage from the lumen of the intestine into the blood.

That the living cells of the mucous membrane are essential to this conversion has been shown by destroying their vitality by dipping the piece of intestine into water at 60° C. After this has been done, the intestinal walls become in fact what it is generally supposed to be during life, a mere filtering membrane.

It is true that a very small per cent. of the peptone formed in the stomach and intestine is not changed into serum-albumin, but even this small amount does not exist in solution in the

blood, but is held by the white corpuscles. The reconversion of the fatty acids, set free by the action of the pancreatic juice, into neutral fats while passing into the thoracic duct is an equally important and interesting fact.

A case of elephantiasis of the left leg with a lymph fistula has recently supplied Munk and Rosenstein¹⁰ with an opportunity of studying the absorption of fats, which has been very thoroughly utilized. From their studies of this case Munk and Rosenstein have reached the following conclusions:

1. The absorption of those fats, which are fluid at ordinary temperature, reaches its maximum between the fifth and eighth hour after a meal, while the maximum absorption of those, which are solid at ordinary temperature, is reached between the seventh and eighth hours. From these hours there is a rapid decrease in the amount of fat in the lymphatics until from the eleventh to the thirteenth hour, when the lowest point is reached.

2. When fatty acids are administered they reappear in the lymph for most part in the form of neutral fats. In this case the body must furnish the glycerine, which is necessary for the synthesis of the fatty acids into neutral fats.

3. The form in which the fat appears in the lymph is determined by the nature of its fatty acid. Thus, both olive oil (triolein) and oleic acid appear in the lymph as triolein, and both tripalmitin and palmitic acid appear as tripalmitin. On the other hand if a fatty acid combined with any other alcohol than glycerine be taken in the food the acid appears in the lymph as a glycerine compound. This was demonstrated to be the case by feeding the patient upon fats consisting of a fatty acid combined with amylic alcohol and at another time spermaceti, which consists of palmitic acid combined with cetylic alcohol. In both instances the fatty acids were found in the lymph in the form of glycerine neutral fats, while no trace of either the amylic or cetylic alcohol could be found in the lymph.

From these facts it is evident that the cells of the absorbing mechanism of the intestine synthesize the fatty acids and in every case the synthesis consists in a combination of the acid with glycerine.

There are many other interesting and valuable points brought out in this research, and I commend its study to you.

It will be seen from the above that all the problems of nutrition are not yet solved, and we are now in a position to at least know why we so often fail to build up an exhausted body by the administration of digestive ferments and predigested food. Indeed, I fear that we may sometimes do harm in our zeal which manifests itself in prescribing peptones indiscriminately. It is

more than likely fortunate that the majority of the so-called peptones in the market consist for the most part of acid albumins and are often wholly free from true peptones.

Here is another medical problem which demands chemical studies for its solution. What is the exact nature of the change whereby peptones are converted into serum-albumin? What are the conditions under which the cells of the mucosa act most energetically? Have we any medicinal agents which may affect this action favorably, or what is of equal importance, are we at present using any drugs which injuriously influence this activity? All of these, and many more which might be asked, are questions of great importance to us as practitioners of medicine.*

Whether or not the digestive ferments ever find their way in any considerable quantity into the blood I do not know. The older physiological chemists have taught us that both pepsin and pancreatin are normal constituents of the urine; but all the experiments upon which this statement rests were made before we had any knowledge of the bacterial ferments, and whether the peptic properties of the urine are due to ferments absorbed from the digestive organs or are products of bacterial activity in the urine after elimination, I think no one knows positively. However this may be, Hildebrandt has recently shown that the digestive ferments, when injected directly into the circulation or subcutaneously, are poisons of marked activity. The fatal dose of pepsin for dogs is from 0.1 to 0.2 grams per kilogram body weight. They produce an elevation of temperature which manifests itself generally within half an hour, reaches its maximum within from four to six hours and may continue for days. The day before death the temperature usually falls below the normal.

The chemistry of the liver has long been an interesting subject of study, and, while many im-

portant facts concerning it have been ascertained, there yet remains much for us to learn. We know that the liver converts ammonia, which should it reach the general circulation in any large quantity would be poisonous, into the practically inert substance, urea. In this organ the poisonous aromatic substances of the intestines, such as phenol, are rendered harmless by being conjugated with the alkaline sulphates.

In studying the changes wrought in the blood during its passage through the liver certain marked difficulties arise. The volume of this blood is so great that it is quite impossible at present to draw any conclusions from comparative analyses of the blood of the portal and that of the hepatic vein, except in the case of sugar. Frogs and birds live for some time after excision of the liver, or after it has been cut off from all communication from other parts of the body by ligatures, but in mammals this operation is followed immediately by death. By means of experiments upon birds, it has been shown that the bile pigments and acids are formed in the liver, the former from the hæmoglobin of the blood, and the latter by the conjugation of glycocholic acid with cholic acid. It is believed that under certain abnormal conditions blood-pigment may be converted into bile-pigment outside the liver, thus giving rise to that form of icterus known as hæmatogenous or chemical, the existence of which, however, has been seriously questioned by the experiments of Vinkowski and Naunyn. Iron is a constituent of hæmoglobin but not of bilirubin. What becomes of the iron which is split off in this transformation in the liver is not known and remains as one of the problems of hepatic metabolism awaiting solution.

Of the chemistry of the nerve cell we know, as yet, practically nothing. Hodge,† in a very interesting series of experiments has shown that stimulation of a nerve going to a spinal ganglion is followed by marked morphological changes in the cells of the ganglion. The nuclei, after being stimulated for some hours, lose forty per cent. of their bulk; the cells themselves decreased but little in size, but their protoplasm became extremely vacuolated and the nuclei of the cell capsule shrank to a noticeable degree. He has also noticed that after the stimulation has been discontinued the cells of the ganglion slowly recover their normal condition. Stress is laid upon the fact that this recovery is very slow, and this, we who have in charge patients who are nervously exhausted, can fully appreciate. There can be no doubt that these visible changes are accompanied by chemical reactions, a knowledge of the nature of which would be of great service, and this forms another of the problems which require chemical studies for their solution. The re-

*Macfayden, Neoricki and Sieber have recently (Archiv. f. exper. Pathol. and Pharm. B. 28, S. 311) made a valuable contribution to the study of digestion. On account of necrosis, due to an incarcerated hernia, an artificial anus was formed at the junction of the small with the large intestine, the excised piece consisting of 10 centimeters of the former and 3 centimeters of the latter. The patient rapidly recovered from the operation, ate all kinds of food and discharged the intestinal contents through the artificial anus for six months, after which time the surgeon joined the ends of the intestine and the natural anus again became the point of exit.

The most important points brought out in the study of this case may be condensed and stated as follows:

1. The contents of the small intestine are constantly acid and not alkaline as has been generally taught and believed.
2. The acidity is due to organic acids produced by the action of bacteria, or the carbohydrates of the food.
3. Bacteria were found constantly present in the small intestine.
4. These germs have but little effect upon proteins, but they produce organic acids and alcohol by their action on carbohydrates.
5. Skatol, indol, and phenol are not formed in the small intestine as has been supposed, but in the large intestine.
6. The same is true of the place of formation of hydrogen sulphide and methylmercaptan. Preparations of bismuth are not blackened in the small intestine.
7. A large amount of fluid injected into the rectum flowed out through the fistulous opening. This happened even when 100 grams of peptone dissolved in 100 cc. of water were injected in two portions. But five eggs, when rubbed up to a homogenous mass with a 0.6 per cent. solution of common salt, the whole measuring 250 cc.), were injected into the rectum in three portions were retained and absorbed.

† American Journal of Psychology, Vol. iii 1891.

searches of Hodge supply a scientific basis for the rest treatment, inaugurated and practiced so ably by Weir Mitchell. When we can ascertain what food and what drugs, if any, best promote the recovery of exhausted nerve cells, another step in advance in treatment can be taken. However, this cannot be done until we ascertain the chemical alterations of which the observed morphological changes are but the outward manifestation.

I have thus briefly pointed out some of the important chemical studies of the nature and activity of the animal cell. The number of these might be multiplied many times. Indeed, in going over this part of the subject I have been embarrassed by the number of illustrations which could be offered, but I hope that these are sufficient to impress upon us a due appreciation of the possibilities which lie before us in this direction.

The Chemistry of Albumin.—Closely allied with the study of the chemistry of the animal cell is the investigation of the constitution of the albuminous molecule, for the latter is an essential part of the former. The researches of Schutzenberger¹ and others have made us familiar with some of the decomposition products of proteid bodies, especially with those obtained by the action of acids and alkalis. Kühne and Chittenden² have enlarged our knowledge of the digestive products, and the experiments of Schröder,³ Minkowski,⁴ and others have enabled us to trace some of the proteids through the animal body. Bechamp regarded urea as an oxidation of production of proteids, and thought that he had prepared the former by the action of potassium permanganate on the latter in alkaline solution. This was in accord with the doctrine of Liebig, who held that all the changes going on in the animal body are those of oxidation. However, Städeler and Loew repeated the work of Bechamp with negative results, and Lossen finally demonstrated that the substance which Bechamp had mistaken for urea is guanidine. Recently Drechsel has succeeded, as has been stated, in preparing urea from casein, and in doing so he has shown that it is not an oxidation, but a hydrolytic product.

Harnack⁵ has obtained chemically pure albumin and has shown that its properties are quite different from those manifested by the impure

bodies which we have hitherto studied. Maschke,⁶ Schmiedeberg,⁷ Ritthausen,⁸ and others have formed crystalline proteids in various vegetable tissue, and Hofmeister⁹ has given us a method of obtaining crystalline egg-albumin. With these advances it is within bounds to predict that the constitution of the albuminous molecule will soon be known. This will furnish us with the key to the arch of animal chemistry, and with this in hand, isolated facts already known, but the significance of which is not understood, will be easily placed in position, and many new and important ones will soon be discovered. The advice of Ludwig, "Study the albumins," is being followed, and will bear fruit in a better and more scientific understanding of tissue metabolism, and this will be followed by a more rational therapeutics.

A thorough study of the proteids is demanded at present, not only for the advanced physiological knowledge which it will give us, but in view of the fact that the most potent bacterial poisons belong to these bodies.*

The Value of Chemical Research in Pathological Studies.—Much of the pathological work of the future must be done by the chemist. In the first place certain chemical agents modify the growth and development of cells. This has long been known to be true in a few diseases. The influence of alcohol beverages in the production of certain abnormal conditions of the liver might be mentioned as an illustration. Chromic acid and the neutral chromates cause necrosis of the cells of the uriniferous tubules. The necrotic cells lose their nuclei, the cell protoplasm becomes a mere net-work and the dead cells from tube casts. Sodium indigotin sulphate injected into the jugular vein of a dog which has been treated with a subcutaneous injection of a chromate does not stain the injured cells of the tubules. Corrosive sublimate also destroys the nuclei of the cells of the uriniferous tubules and produces a pseudo-diphtheritic combination of the intestines. At the same time, this poison produces marked changes in the medulla of the bones and induces a general anæmia. The effects of lead on the cells of the brain have been frequently observed: Vulpian¹⁰ found colloid degeneration and atrophy with multiplication of the nuclei; while Monakow,¹¹ Oppenheim¹² and others have reported extensive degeneration and disappearance of the cells of certain ganglia. The karyolytic necrosis of the cells of the uriniferous tubules caused by acetone has been described by Albertoni and Pissenti¹³ and explains the albuminuria which oc-

¹ Bulletin de la Société Chim. T. 23, p. 161, et seq. Zeitschrift f. Biologie, B. 22, S. 423 et seq.

³ Loc. cit.

⁴ Berichte der Deutschen Chem. Gesellschaft

⁵ The study of the products formed by the bacterial splitting up of proteids will probably be of service in ascertaining the constitution of the albumin molecule. Netcki has found that certain aerobic germs produce from albumin the three aromatic acids: 1, phenylpropionic, 2, paraoxyphenylpropionic (hydroparacumic acid), and 3, skatolacetic. From this he concluded that the albumin molecule contains, preformed, not two, but three aromatic groups, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

curs in severe cases of diabetes mellitus. The ill effects of some preparations of digitalis is explained by the well demonstrated, poisonous action of digitoxine on certain cells. The destructive effects of many chemical substances such as the arsenide of hydrogen, bile acids, etc., on the blood corpuscles is well known.

These and many other substances which might be mentioned, cause marked changes in the cells of the living body, and new interest is now attached to this point by the discovery of the fact that some of the ptomaines, those of cholera for instance, manifest their activity in this direction. Since it is now generally conceded that all pathogenic germs induce their characteristic effects by virtue of chemical poisons which the microorganisms elaborate, the chemist and histologist must become co laborers in pathology. The bacteriologist will discover, isolate and study the life history of the germ. The chemist will isolate the active poisons produced by the germ. The physiologist will study the effects of these poisons. The histologist will make us acquainted with the morphological changes produced in various organs. Finally, let us hope, the therapist will gain from all these contributions some information which will make the practice of medicine both more scientific and more successful than it is today.

In the second place, we have positive proof that under some abnormal conditions the chemical activity of the living cell is perverted. This perversion may manifest itself, 1 by an abnormally abundant production of certain compounds, 2, by failure to produce changes which are affected in health, and 3, by the elaboration of new products.

The increased tissue metabolism of the acute fevers, in poisoning with phosphorous, arsenic, antimony, carbon monoxide and chloroform, and in carcinoma, are illustrations of the first of the above mentioned facts. In health the amount of nitrogen in the ingesta and that in the egesta are practically the same. This normal condition of "nitrogen equilibrium" is disturbed in the above mentioned abnormal states. The agent which causes this increased disintegration in the albuminous molecule is certainly not the same in all cases. In many, its character remains unknown and we must depend upon the researches of the chemist for information in this important field of pathology.

The abnormally large amount of uric acid and allied bodies in the urine in leucocythemia is undoubtedly due to the increased number of nuclear cells, but what the active agents are which lead to the excessive formation of nuclear tissue we do not know. However, that they are chemical in character is suggested by the fact that a leucocythemic condition is produced in some of the acute infectious diseases (diphtheria for in-

stance) in which the actual *materies morbi* is a chemical poison.

The fact that cells under abnormal conditions may fail to elaborate their normal products is shown by the absence of hydro-chloric acid in the secretions of the stomach in cancer; while the appearance of acetic acid, oxybutyric acid and acetone in the urine in diabetes mellitus is an illustration of the formation of new products in disease.

The causes of coma in diabetes, pernicious anemia and carcinoma are unknown. That this coma occurs without any recognizable morphological lesion in the brain has been proved by Oppenheimer,⁴ and the fact that all of these diseases are accompanied by increased metabolism of the nitrogenous tissue renders it highly probable that the nervous symptoms are due to the action of a chemical agent.⁵

THE TREATMENT OF THE FIRST STAGE OF ACUTE LOBAR PNEUMONIA.

Read in the Section of Practice of Medicine and Physiology at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May 28, 1891.

BY J. W. SMALL, M.D.,

OF NEW YORK, N. Y.

FELLOW NEW YORK COUNTY MEDICAL ASSOCIATION; FELLOW NEW YORK STATE MEDICAL ASSOCIATION; FELLOW AMERICAN MEDICAL ASSOCIATION; FELLOW NEW YORK ACADEMY OF MEDICINE

In an editorial article in one of our leading medical journals an eminent writer has recently said that the "treatment of acute lobar pneumonia is still a reproach to our art, even more so than phthisis pulmonalis, and there is no subject which deserves more earnest study." To the truth of this statement every practical physician who reads the current literature upon this subject can testify. The pathology of this disease is indeed very well understood, but the diversities in the methods of treatment applied are almost as many as the physicians who employ them.

In presenting this subject for your consideration in this paper, I propose to deal only with the first stage, or that preceding the stage of red hepatization. The very simple treatment outlined does not, indeed, do any harm, but often much good, if used after the affected portion of the lung is solidified, but of that I do not propose to treat, but simply record the results of my own experience in treating the first stage as a local congestion and inflammation of lung tissue. So many methods have been tried and remedies used to abort this disease, that it would be impossible for me to enumerate all of them, but I will consider a few before describing the very simple method of treatment with which I have succeeded in ar-

⁴Churche Annalen, 1888.

⁵It was the intention on beginning this paper to devote a considerable portion of it to the chemistry of therapeutics but this subject is now reserved for a future paper.

resting it. And my method is so simple that I fear many of my professional brethren will throw this paper by with a feeling of contempt; yet not, I hope, until they have made a thorough trial of the method described. Is it not a fact, my brethren, that we are too apt to overlook those simple remedies and methods of treatment with which we are perfectly familiar, and reach out for these specifics with large-sounding names which are recommended by those high in the profession, and which we so often find to be fallacies that sadly disappoint us. The name of a Brown-Séquard or a Koch has a peculiar fascination for us, while the patient life-work of a humble practitioner, containing practical lessons of the richest value, is entirely overlooked and soon forgotten.

Probably the remedy which has been most frequently tried to abort this disease is quinine, given in doses of from 10 to 100 grs. and repeated *ad libitum*. This has no doubt been given with the idea that the disease is one of malarial origin. But Dr. J. H. Ripley, in a paper read before the New York Academy of Medicine, and reported in the *Boston Medical and Surgical Journal* for 1887, Vol. cxvi, p. 212, has shown us that he has found by careful experiments made at St. Francis' Hospital, that quinine does not abort the disease and does not act as an antipyretic, but has a bad effect upon the appetite and digestion, is liable to produce cardiac weakness, profuse cold perspiration and profound nervous debility. This testimony is corroborated by Dr. H. Corson in the *Medical and Surgical Reporter* for 1887, Vol. lvi, pp. 644-647. My own experience has not been favorable to its use in the first stage of this disease.

Dr. H. S. Duncan, in the *Nashville Journal of Medicine and Surgery* for 1885, Vol. xxxv, pp. 154-160, recommends blisters on the affected side with calomel and veratrum viride. This treatment has been largely used by physicians, but never to my knowledge with the effect of shortening the disease, but may modify its severity. Dr. F. L. Benham, in the *Medical Times and Gazette*, London, 1885, Vol. 1, pp. 73-76, makes an argument in favor of blood-letting and antimony—withdrawal at the first venesection from 10 to 12 ozs. of blood, and repeating the process in from twelve to twenty-four hours. This treatment is based upon the old-fashioned antiphlogistic theory of blood-letting for inflammation, but is not claimed to abort the disease, but simply modify it. To the employment of venesection in any form I should have very serious objections, as I consider it a measure calculated to produce extreme prostration of the system by depriving it of what little vital fluid is left after its depletion by the disease, and after the commencement of the second stage I regard it as positively dangerous.

Some writers in the *London Lancet*, and Dr. Fricand, writing in *Duodecim*, a Finnish medical journal, have advocated the application of ice lo-

cally over the affected portion of lung by means of rubber bags filled with it, and giving opium expectorants and stimulants internally. With this treatment it is claimed that only three deaths occurred in one hundred and six cases, but it is not claimed that it materially shortens the disease.

In a case reported in the *London Lancet* for 1889, Vol. 1, p. 730, Dr. H. E. Counsell shows the apparent abortion of pneumonia in its first stage in a patient aged 21 by a single dose of 15 grs. of antipyrin given at bedtime. As this is the only case which I can find recorded where the inflammation has been broken up, and as it so much resembles many of my own cases, I have strong hope that this class of antipyretics may render valuable assistance in the treatment of this disease.

I will now give in detail my own theory and practice in this disease; one which I have used for twenty years and in several hundred cases, and, when the patient has been seen before the second stage, with always the result of breaking up the disease within twenty-four or forty-eight hours.

Upon the causation and pathological character of pneumonia all medical authorities are well agreed. Previous to that time when the air cells become occluded with an inflammatory exudation consisting of fibrillated fibrin, pus cells, red globules and changed epithelial cells, the affected portion of lung tissue is in a state of active congestion or pulmonary engorgement. Could we examine the fine capillary blood-vessels of the alveoli and minute bronchi, we would find them distended to their utmost capacity with blood, venous blood, which instead of passing through the pulmonary circulation and becoming oxygenized, remains localized, thus impeding the process of respiration and taking on inflammatory action. The temperature of the affected portion of lung is far above normal: its action is obstructed so that it is impossible for the blood to become aerated, and the only relief which can possibly come to the overburdened lung tissue is that which Nature offers by throwing into the alveoli and bronchi the inflammatory products of the blood, thus placing the affected part at rest while Nature takes time to undo the mischief she has wrought in her efforts for self-preservation. But is there no way to bring relief to the overburdened lung except the one which Nature adopts? I answer positively, yes. There is a way, and a certain way, to remove this localized congestion, if made use of before these pathological changes have taken place which fill the alveoli and bronchi with inflammatory products, and it is accomplished upon the well known principle that congestions within the thorax or abdomen are always relieved by actively stimulating the venous and arterial capillary blood-vessels upon the surface of the body and at the extremities. This active stimulation

of the surface capillaries quickly removes from the part the blood pressure by bringing the blood to the surface of the body and thus equalizing its circulation. In order to accomplish this practically I have prepared a tub or pail partially filled with hot mustard water. Seating my patient on a chair, or the edge of the bed, I have him thoroughly covered with blankets. Then I have the feet, legs, thighs and arms thoroughly rubbed with the hot water, using it as hot as it can be borne and gradually working the feet into it, rubbing them until quite red; then putting the patient into bed and covering warmly with blankets, with a rubber bag or jug filled with hot water at his feet. I then have made three large, hot poultices of flaxseed meal, or rye flour well sprinkled with mustard and a little ginger and covered with a piece of thin muslin. One I have placed over the thorax in front, one behind, between the shoulder blades, and the third upon the affected side over the region of the pain. I keep my patient well covered with an extra quantity of bed clothing, being very particular to have him keep his arms and hands well covered, and watch results. In from one-half hour to two or three hours he will be in a profuse warm perspiration, and in from twelve to fifteen hours the pulse, respiration and temperature will be reduced to nearly normal. In the great majority of cases I believe this treatment alone sufficient to break up the congestion and pyrexia if adopted early. But it has usually been my practice as soon as my patient is in bed after the foot bath to give a powder composed of equal parts of nitrate of potassa and Dover's powder—for an adult five grains of each, and repeat in three hours if free perspiration does not occur. I have recently obtained good results from a powder of fifteen grains of antipyrin used once, but not repeated, as I have found the repetition apt to produce an unfavorable action upon the stomach and great depression. In fifteen minutes after giving the powder, I commence with tr. aconite rt., in doses of from gtt. ss. gtt. iss., with spts. æth. nit. gtt. xv and water to one teaspoonful. These doses I give every half hour or hour as the urgency of the case demands until I have given six or seven doses, then repeat at intervals of two hours. With children, instead of the poultices of flaxseed and mustard, I have used onions and lard with excellent results. In other respects their treatment has been precisely similar. This treatment, when used early, I have never known to fail, and I have sometimes used it with success two days after the initiatory chill. When called to a patient in the afternoon or evening I have found the next morning the pulse reduced from 120 to 80 or 85, the temperature from 103° to 99° and all symptoms of fever disappearing within the next twenty-four hours.

THE TREATMENT OF SPASMODIC ASTHMA.

Read in the Section of Practice of Medicine and Physiology at the Forty-second annual Meeting of the American Medical Association, held at Washington, D. C., May 1, 1891.

BY J. F. JENKINS, M.D.,
OF THURMSH, MICH.

In dealing with this subject, it will be unnecessary for me to enumerate the many remedies which are in vogue in the treatment of this obstinate and distressing disease; neither will it be necessary to mention the beneficial results which are often produced upon the patient's health by a change of climate.

My object in the preparation of the paper is to bring to your notice a remedy which has, within the last few years, been prescribed for the purpose of mitigating the attacks of asthma. The remedy alluded to is *euphorbia pilulifera*, a plant which grows by the way-side in Australia, and which, according to Australian medical literature, has been used as a domestic remedy in the treatment of asthma and bronchial affections by the inhabitants of that island.

The universal experience of all who have practiced the healing art for a number of years is, that old and tried remedies frequently fail to give relief, and we are frequently driven from one remedy to another, in order to mitigate the sufferings of a patient who is undergoing an attack of spasmodic asthma, and who is bound to get relief, if not from the profession, he will seek the advertised charlatan, or the quack nostrums of the day.

In order to make my remarks as brief as possible, and to make this paper practical without being verbose, it will be necessary to give the clinical history of a few of the cases which have come under my observation, and have been treated by this drug.

Case 1.—George S., age 45 years. Came under my observation January 9, of this year. He states that he has had frequent attacks of asthma during the past ten years, and during the last three years, the paroxysms have been more frequent and severe. After a careful examination of the chest, there was no evidence of structural changes in either heart or lungs. The kidneys were in a healthy condition, the appetite good, and the bowels regular. In fact, he was in the enjoyment of good health (as he expressed it), if it were not for these periodical attacks of asthma. He was ordered a mixture of equal parts of the fluid extract of *euphorbia pilulifera* and glycerine, with directions to take a teaspoonful every four hours during the day, and to report in the course of a week or ten days. When he returned to my office, he stated that he slept well at night; has had no return of paroxysms of asthma; found one or two teaspoonfuls

a day sufficient to ward off the attacks. States that he has not slept so well for years.

This patient has been under observation up to within a few days, and has been thus far relieved from the annoying paroxysms of asthma.

Case 2.—Mrs. Z., age 50 years. An American by birth. Has usually had fair health, but during the past seven years has had frequent attacks of asthma. During the past year, she states that the attacks have been more frequent and severe, especially during the autumn and spring. No organic disease of either heart or lungs could be detected upon examination of the chest. There were no structural changes in the kidneys. Appetite and digestion fair. This patient had been previously under treatment for asthma, and at that time the paroxysms were mitigated by a combination of *grindelia robusta* and iodide of potassa. At this time she was given a mixture of the fluid extract of *euphorbia pilulifera* and glycerine, equal parts, of which she was to take a teaspoonful every four hours during the day, and in the course of a week to report. When the patient returned to my office she stated that the paroxysms of asthma had ceased under the influence of the medicine, and that she had rested quietly all night in the recumbent posture, while heretofore it was impossible to sleep without being propped up in bed.

Case 3.—Mrs. A., age 43 years, weight about two hundred pounds. American by birth. Has frequent attacks of asthma. Heart and lungs sound. Appetite and digestion good. Suffers more from asthmatic attacks during autumn and winter than any other seasons of the year. Frequently obtains relief by inhaling the fumes of burning nitre of paper. Prescribed the fluid extract of *euphorbia pilulifera* and glycerine, equal parts, of which the patient was to take a teaspoonful every three hours. Her husband reported that the medicine had no effect on the paroxysms of asthma, and that his wife's asthmatic breathing was relieved by smoking cubeb cigarettes.

Case 4.—Miss R., age 13 years, has suffered from asthma from early childhood. Has received treatment from all sorts of physicians, from the cultured physician as well as the travelling mountebank, and has obtained very little benefit from any of them. No organic disease could be detected of either heart or lungs, upon examination of the chest. No structural changes in the kidneys. Appetite and digestion fair, and the patient well nourished. She was prescribed a mixture of equal parts of the fluid extract of *euphorbia pilulifera* and glycerine, with directions to take a teaspoonful morning, noon, and night. Her mother reports that the daughter has breathed better, and suffered less from asthma than at any period for several years.

Within the past year thirteen cases of spas-

modic asthma have come under treatment, and in each case the fluid extract of *euphorbia pilulifera* has been prescribed with satisfactory results, except in one or two cases where it failed to relieve, although no cause could be assigned for its failure. There were no complications, but the drug failed, like many others which have a decided influence in the treatment of spasmodic asthma. In one instance, where mitral lesions were present, a pill containing one one-hundredth of a grain each of trinitrin and strophanthin, night and morning, in connection with half a drachm of the fluid extract of *euphorbia pilulifera* every four hours during the day, gave the patient relief from the paroxysmal attacks of asthma, which were no doubt of neurotic origin.

Finally, permit me to briefly state the conclusions arrived at by Dr. John Aulde, of Philadelphia, who has prescribed *euphorbia pilulifera* in twenty-five cases of spasmodic asthma: "*Euphorbia* is a remedy of special value in the treatment of all forms of asthma. In the absence of organic changes in the pulmonary and renal structures, and when the atmospheric conditions are favorable, relief will usually be afforded after taking the first dose. Being excreted largely by the liver and kidneys, the condition of these organs must be taken into consideration when estimating the probable effect of the drug. It has no special action in controlling the sudden attacks, but may be depended upon in young and robust individuals to effect a radical cure, providing they will continue to reside in an atmosphere that is dry and bracing, situated in a moderately elevated locality, where there are no, or comparatively few, sudden changes."

FOREIGN CORRESPONDENCE.

LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

The late Mr. Richard Middlemore—The Statistics of the German Government on the Koch Remedy—The Oldest Living Surgeon—Prof. Victor Horsley on Hydrophobia—The Effects of Fog on the Manchester Atmosphere—Discussion on Strangulated Hernia—Report of the Trustees of the Peabody Fund.

Mr. Richard Middlemore, of Birmingham, who died in his eighty-seventh year, was a leading ophthalmist, and author of a treatise regarded as the handbook of ophthalmology, to promote the knowledge and practice of which in Birmingham he contributed with his efforts and his purse. In 1877 he founded a prize to be awarded triennially by the Council of the British Medical Association, for the best essay on "The Scientific and Practical

Value of Improvements in Ophthalmic Medicine and Surgery."

Official reports on Dr. Koch's much contested remedy somewhat correct the reaction which has set in against the treatment. The German Government has obtained statistics from fifty-five hospitals, where during eight weeks 2,172 patients were treated with 17,500 injections of the lymph. The maximum injections for one person were fifty-four, and the largest dose 3.826 grams. Of 1,061 patients suffering from internal tuberculosis 13 were cured, 171 much improved, 194 slightly improved, 586 no better, and 46 died. Out of 708 sufferers from external tuberculosis 15 were cured, 148 much improved, 237 slightly improved, 268 no better, and 9 died. Owing to the reported failures, the "tuberculin" is in little demand from the Berlin chemists, while at Madrid the committee appointed to examine the treatment have checked any further experiments. The only success reported from Spain is stated to have been with lepers and persons suffering from lupus of the face.

Mr. William Salmon, of Prullyn Court, Cowbridge, Glamorganshire, has just attained his 101st birthday. Mr. Salmon is the only known centenarian Freemason, and there can be little doubt that he is now the oldest member of the craft. Mr. Salmon is also thought to be the oldest living member of the Royal College of Surgeons. He was born March 16, 1790.

Professor Victor Horsley has given a discourse at the Royal Institution on "Hydrophobia." The professor began by remarking that it was Pasteur who first proved that hydrophobia was due to a "germ." These germs, when numerously developed in a dog, might be communicated by the saliva, but it had been observed that dropped saliva speedily lost its power of communicating rabies on drying. The time from inoculation to the development of the disease was not less than six weeks, but it might be two years, and it was this dreadful suspense that formed one of the horrors of receiving a bite from a dog suffering from rabies. Professor Horsley considered there were two well-marked, distinct forms of hydrophobia, the excitable and the comatose. In rabbits it always took the comatose form. Dogs might have either form, and at the Brown Institute and the Dog's Home he had studied both forms. In the furious form an animal, however domesticated, runs away, and it was by these stray dogs that the disease was spread. The professor gave some details of the symptoms a dog shows, and alluded especially to the entire change in appetite. The professor pointed out that wherever the muzzle had been long in force the disease had been stamped out. A diagram for English deaths showed that there was a fall in deaths from rabies after 1885, when the muzzle was obligatory, and a rise after 1886, when the order

was withdrawn. There was also a fall after 1889, when the muzzle was again ordered. The experience of Vienna was the same. Prussia had maintained the muzzle, and had but two deaths when in England there were eighty. He hoped the Government would re-order the muzzle. When rabies had once developed there was no known cure. Pasteur's method of inoculation, he said, had saved 94 per cent. of bitten people from having rabies.

The effects of fog have been very disastrous this winter on the Manchester atmosphere. According to observations taken during three days of fog, nearly six hundred weight of sulphuric acid per square mile was deposited around the Infirmary, besides two hundred weight of hydrochloric acid and two tons of blacks. The leaves of plants growing out of doors near the hospital yielded a deposit of from 6 to 8 per cent. of sulphuric acid, and 5 to 7 per cent. of hydrochloric acid.

In a discussion at the recent meeting of the Royal Medical and Chirurgical Society on the treatment of strangulated hernia when the intestine is gangrenous or ulcerated, Mr. Treves, referring to the occasion in 1885 when Mr. Mitchell Banks had brought up the same subject, said everyone must have been struck with the remarkable differences of opinion then expressed. No doubt this was due, he thought, to the fact that in any individual's experience such cases were comparatively rare. The statistics of mortality between the old method and primary resection were not comparable. The first series with a mortality of 90 per cent. was absolutely perfect, being taken straight from hospital records, but the second, taken from McCosh's tables, with a mortality of 50 per cent., were selected cases. Mr. Treves thought the mortality after resection was at least 90 per cent., for if the mortality after resection was only 50 per cent. it would be about the same as that of the ordinary operation. It was highly improbable that it was no more dangerous to resect than to open the sac. Surgical instinct was always opposed to resection, although the two first recorded cases—the first by Ramdorn, in 1727, and the second by Arhand, in 1732, which represented the old method, were both perfectly successful. Mr. Dean, of the London Hospital, looked up for him the cases of strangulated hernia which he had operated upon; there were 73 in all. Of these six were gangrenous and all had died. Two were left on account of there being general peritonitis. In one the bowel was opened and in the others the whole of the gangrenous parts, two inches, three inches, and eighteen inches respectively he had resected. In McCosh's tables the average duration of the operation for resection was from one and a half to two hours, and often had to be performed when the parts were bathed in putrid pus. He thought that in

acute intestinal obstruction the less done the better the result, as the patients were not dying of gangrene but of obstruction. Mr. Treves went on to say that he had come to the conclusion that the best and simplest way was merely to open the sac and divide the stricture so as to relieve the obstruction. If the intestine was found to be gangrenous it should be brought gently down and attached by sutures to the abdominal wall and then either open the gut or let it open itself. To pull down the gut he had found to be a very dangerous proceeding.

To read the twenty-sixth annual report of the trustees of the Peabody Fund is to realize what a gigantic work it is to properly house the poor of London. Mr. Peabody's benefactions amounted to a total of £500,000. To this round sum the trustees have added by way of rent and interest £523,446, and they have expended in all, including money borrowed, £1,233,845. The result is the provision of 11,275 rooms occupied by 20,462 persons. The average rent paid is 2s. 1³/₄d. As a rule the health of the model dwellings is better than that of London generally, but owing to the epidemic of last spring, from which many of the tenants suffered, the death-rate in 1890 is slightly above the average of the metropolis.

The Chair of Anatomy at the Royal Academy has been conferred upon Mr. William Anderson, of St. Thomas' Hospital. Mr. Anderson was for some years medical director of the Imperial Medical College of Japan, and is well known as the author of a classical work upon the early Japanese artists.

The Hospitals' Association has just established their fiftieth street ambulance station in the portico of the Royal Exchange. The Association is now largely extending its organization and the committee have under consideration the establishment of twenty-seven additional stations suggested by the chief commissioner of the metropolitan police, on the recommendations of the superintendents of the different divisions. These stations are in various quarters of the metropolis, but mainly in the East End, in which district the association's organization is as yet least complete. The completion of these new stations will see the whole of London furnished for the first time with a complete street ambulance service.

TO REMOVE THE PIGMENTATIONS OF PREGNANCY.

In the *Journal de Médecine de Paris*, January 4, 1891, the following ointment is recommended to be rubbed into the affected parts twice daily to remove the pigmentations which so often disfigure pregnant women:

- R. Cocoa butter,
- Castor oil, aa 3 ij 4.
- Oxide of zinc, gr. v.
- Yellow oxide of mercury, gr. ij.
- Essence of roses enough to perfume.

STATE MEDICINE.

Michigan State Board of Health.

The annual meeting of the Michigan State Board of Health was held at the Capital, Lansing, Mich., April 14, 1891. Prof. Fall, Drs. Avery, Hazlewood, Vaughan and Baker were present. Dr. Avery was reelected president.

DR. VAUGHAN reported that, at the State Laboratory of Hygiene, he has made analyses of all the different kinds of baking powder found in the market, also of one hundred and twelve samples of water from different parts of the State, and that he was ready to report the results, also of his researches on typhoid fever.

DR. BAKER reported that he had worked out the cause of influenza. He said its greatly increased prevalence during the last three months is alarming because so many other diseases follow that disease, and increase after it increases, the diseases which so increase being consumption, pneumonia, cerebro-spinal meningitis, rheumatism, osteo-myelitis, etc., influenza seeming to bring in its train all of these most important diseases. Dr. Baker explained the causation of influenza. He stated that the germs of influenza are generally, at all times, present, and the germs of pneumonia, tuberculosis, and of the other specific diseases are somewhat widely disseminated; but that there must be certain coincident meteorological conditions to irritate the throat and air-passages sufficiently to let the germs gain an entrance to the body. These meteorological conditions in this instance, were the excessive prevalence of north and north-east winds, and the excessive amount of ozone during the past three months.

The prevention of influenza and of the coincident rise in the other more dangerous diseases, has not been possible, because of ignorance of the causes. Now the causes are known, and the study of the measures for the prevention can begin.

How to get more thorough disinfection after contagious diseases, was brought up by Dr. Hazlewood, also by letter from Dr. Nicholson, of the Upper Peninsula, and also by other correspondence of the office of the board. It seems to be made plain that, if the Bill now before the Legislature (Senate Bill 257, House Bill 640) shall become a law, making a small appropriation to enable the State Board of Health to send an inspector to the localities where most needed, to aid in the final disinfection after cases of dangerous diseases, the spread of those diseases can be very greatly lessened, and hundreds, and possibly thousands of lives can be saved in Michigan in every year.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

NO. 68 WARASH AVE.,

CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the Treasurer, Richard J. Dughson, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, MAY 23, 1891.

THE ADJOURNED MEETING OF THE TRUSTEES.

The Trustees of the Association met in Chicago on Wednesday, May 13th, all being present except Dr. Shoemaker, who was represented by proxy. The question of appointment of Editor being taken up, Dr. J. C. Culbertson, for many years editor of the *Lancet and Clinic* of Cincinnati, was placed in nomination and received the unanimous vote of the Trustees.

Dr. Culbertson was also instructed to act as Business Manager.

On Thursday, May 14th, the Trustees, in company with the newly elected editor, inspected THE JOURNAL office, and he was formally placed in charge.

The Trustees bespeak for Dr. Culbertson the same kindly consideration that has been extended to his predecessors, and they feel sure that the results of the new management will show the wisdom of their selection.

By direction of P. O. Hooper, President of the Board. JOHN B. HAMILTON, Secretary.

MEDICINE AND THEOLOGY.

It is in the best sense commendable for every physician to join some church of his choice, and by example and act, do all he can to build up the higher life of the community, and also encourage its ethical culture and growth. When the physician becomes a church partisan, and ar-

dent defender and propagator of certain creeds or doctrines, he must to some degree lay aside his scientific training and reputation. When, on the other hand, the physician ignores all church influences, and assumes skepticism and doubt, sneering at all church efforts, and teachings of the Bible, he very clearly exhibits his narrow judgment and scientific incompetency.

The physician should never forget that he should be a student of all science, in the broadest meaning of that term. In that position he must accept the general facts and principles of theology, as clearly settled as any other knowledge in the world. He may not be convinced of this or that form of church doctrine, or interpretation of Biblical teachings, but he should ever hold the subject open for further evidence, and always show a readiness to hear all sides of the topic.

The majority of medical men have long ago taken this position, and where they do not become active members of some regular church, are reverential believers and supporters of the fundamental principles of Christian religion. It is only the minority, which happily are growing less every year, who are skeptics, and who hide their weakness under the pitiful expression of *Agnosticism*. These men are always urging the idea of conflict between science and religion, which every true student of science denies, and every new truth of nature flatly contradicts. Learned theologians and scientists find no conflict or clash of the great truths of nature and theology; only the small, weak, half-learned men are troubled by such possibilities.

Medical men are more fortunately situated than others to realize and understand the higher ranges of physical and physiological laws, which are active in the formation of life and character, and the many unknown forces which enter into the religion of life in its higher sense. We believe no class of professional men are more reverential and so profoundly impressed by the operation of nature's laws, and the spirit forces of the world.

A noted New York surgeon whose reckless, abrupt manner was the subject of comment, was giving a clinical lecture when the patient suddenly died. Being a jocular man, who saw the grotesque in all things, every one was hushed in expectation of some remark. He stood silent a few moments, then turned to the class with tears in his eyes, and in a choked voice said: "You

have witnessed a phenomenon which will be a reality to each one of you, some day. If you are true men and live right, it will be welcomed, and not dreaded," and walked out.

These remarks are suggested by the sad comment of a noted college President, that medical men are becoming more skeptical and dangerous to the growth of ethical truth. In reality this is the exact opposite of the facts. Statistics will show that more physicians are both active and passive church members, than ever before. In every town and city in the country medical men will be found actively supporting almost every Christian and philanthropic movement for the elevation of the people. The real students of all the writings of DARWIN, HUXLEY, SPENCER and others, will never be skeptics or obstructionists to ethical truth. The half-learned are the only dangerous men. Medicine and theology will never be in conflict or suffer except from this class. Both medicine and theology are rapidly changing, and breaking away from much of the narrow superstition of the past.

The province of the physician is more and more a teacher, and less a dealer of drugs. The clergyman is coming nearer the physician, and both are pointing out and applying the higher laws of physical and spiritual life, and urging men to live in accordance with them. The highest form of theology points out the realm of the spiritual, from the physical, and shows the laws and forces which govern the life here and hereafter; and the highest form of medicine indicates the reign of physical laws, their scope and influence, over organic and tangible life.

While theology carries the range of study farther on, it is no less obscure or doubtful than medicine of to-day. The dogmatic medical man who assumes that he possesses positive knowledge of physiology, pathology and therapeutics, is on the same range of the theologian who teaches the completeness of all spiritual truth. Both are incompetent to judge of the range of study of the other, and both fail to comprehend the spirit of truth, or understand the great principles of evolution and growth, and human conceptions of truth.

The unfortunate church war which is going on in an Eastern city, in which a number of physicians have become involved, has no medical or theological significance, but merely reflects the

weakness of both sides, and can result in no possible good whatever. Toleration, generosity, a spirit of benevolence, and full recognition of the right of private belief, should exist in both clergymen and physicians. Happily this is the rule, of which only a few exceptions occur. The clergyman and physician should draw nearer with every advance of science. The mutual influence of one upon the other would go far towards elevating the race and lessening the tides of disease and misery.

THE PROBLEM OF WATER PURIFICATION.

Perhaps the most important sanitary question now pressing for solution is that of a pure water supply for our towns and cities. As this country becomes more populous, the streams and lakes receive more refuse and sewage, until the purification of the water supply for a given locality has become the crying need. Statistics show that at least 55 per cent. of the waters supplied to cities and towns are obtained from surface sources and are necessarily liable to more or less contamination. Various remedies have been sought for this condition, the most practical thus far suggested is to prevent the contamination, by carefully guarding the lakes or rivers from which the supply is obtained. It is at once apparent that only a certain degree of security is reached in this way, as it is clearly impossible to perfectly guard an extended water shed.

Aside from organic or infectious pollution, surface waters frequently contain fine particles of inorganic matter in suspension, or they are more or less discolored and so rendered unsightly and distasteful. This is especially true of many river waters, even when they are wholesome so far as health is concerned. Natural springs with deep wells have been considered the best sources of water supply, but unfortunately their range is limited and they offer no practical solution of the water supply of our larger towns. If we consider for a moment the sources of spring water we find that it was originally precipitated upon the surface, but as it percolates through the sand, gravel and stratified rocks it gradually loses its suspended matter and becomes clear and sparkling. The earth acts as a great natural filter and waters found at any considerable depth are usually free from dangerous contamination, unless there has

been sufficient pollution of the surface to extend some depth into the soil.

In the treatment of polluted waters this natural process should as far as possible be imitated, and we believe that it is precisely upon these lines that the solution of our water supply problem is to be reached. Filtration, however modified, has always been based upon one principle, that of forcing water through a substance with pores sufficiently fine to entangle the suspended organic and inorganic matter. Almost every conceivable porous substance has, at one time or another, been used in filtering water. These, however, may be divided into two classes: first, those consisting essentially of a porous plate or bed, such as sandstone or unglazed porcelain; and secondly, those in which a porous mass is formed by a substance in a fine state of subdivision, such as sand, gravel or charcoal. So far as we know, the first class have never been used on a large scale, though good results have been obtained where but a limited supply of water is required. The chief objection to filters of this class is that the interior of the bed or plate cannot be cleaned. Laboratory experience shows that bacteria soon make their way through plates of this kind. A further serious objection is that they cannot be adopted for the filtration of water upon a large scale.

The sand filter in its various modifications is the only one that has been adopted in the filtration of waters for towns and cities. Excellent results may be obtained by simple beds of sand, allowing the water to flow over the surface and percolate through to a suitable collecting chamber below. Filters arranged upon this plan purify most of the water supplied to the city of London. The chief objection to gravity sand filters is their great size, and cost of maintenance. The outer layer of sand must be removed every few days and fresh sand substituted; and, unless the bed is carefully prepared and the water evenly distributed over the surface, crevices will form, through which the water flows without filtration.

A modification of the sand filter is one in which the bed is surrounded by a shell, and the water is forced through by hydraulic pressure; this force if sufficient forms the sand into an evenly resistant compact mass, comparable to a very soft sand-stone. A filter constructed upon these principles and filled with fresh clean sand will

give a pure sparkling water for some hours, but the outer layers soon become foul and clogged, and little or no water can be passed through; it is therefore necessary to either renew the sand or to have some means of thoroughly and efficiently cleaning it. It is just at this point that inventors and engineers have failed. It is apparent that a filter constructed upon such principles, if the bed cannot be thoroughly cleaned, is worse than useless, it becomes indeed a positive source of danger; it is this defect that has rendered some of the devices now on the market worthless.

It has been demonstrated that a simple bed of sand arranged in this way will remove all suspended matter and most of the bacteria. Can we not look for mechanical devices that will easily and cheaply cleanse this sand? This once accomplished, one of the greatest sanitary problems of the age will be solved, and public health have taken a long step in advance.

EDITORIAL NOTES.

SOME of the ways adopted by other large assemblies and organizations may be profitably imitated in future meetings of the American Medical Association, as indicated by the ease with which ill-digested resolutions are sometimes passed in our general sessions suggests the necessity of having in amendment to the By-Laws of the Association, whereby *all* resolutions before being voted upon, shall have been previously introduced and referred to a committee on resolutions. By having such a committee it would be quite impossible to pass resolutions under the spur of insufficient time for consideration. Nobody would be wronged by such a course, for the committee by the terms of its organization should be required to report back to the Association, either by favorable or adverse report, all resolutions referred to them not later than the morning hour of the last day of the session.

TO BE TRIED UNDER THE CODE.—A San Francisco physician, member of the San Francisco County Medical Society, read a paper before that body and the following day extensive abstracts of his contribution appeared in the daily public press, presumably with his knowledge, consent and assistance. Charges were promptly brought against him for a violation of the Code of Ethics, and his trial was set for an early date.

AMERICAN MEDICAL ASSOCIATION.

Forty-second Annual Meeting, held at
Washington, D. C., May 5-8, 1891.

FOURTH DAY—FRIDAY, MAY 8.

The President called the Association to order at 10 A.M.

Prayer was offered by Rev. Dr. John H. Elliott, D.D.

The Permanent Secretary read the names of the committee to petition Congress, as per resolution, on a Secretary of Public Health.

Committee: C. G. Comegys, Chairman, Ohio; J. F. Hibberd, Indiana; N. S. Davis, Illinois; J. C. Culbertson, Ohio; T. G. Richardson, Louisiana; Wm. B. Atkinson, Pennsylvania; Chas. A. Lindsley, Connecticut; C. A. Hughes, Missouri; Wm. T. Briggs, Tennessee; H. D. Didama, New York; Thos. B. Evans, Maryland; Alex. J. Stone, Minnesota; J. P. Logan, Georgia; W. W. Kerr, California; Chas. Jenison, Colorado; W. L. Schenck, Kansas; P. O. Hooper, Arkansas; H. J. Swearingen, Texas; Wirt Johnson, Mississippi; Thos. F. Wood, North Carolina; J. N. McCormack, Kentucky; J. T. Reeve, Wisconsin; H. O. Walker, Michigan.

Officers of Section on Obstetrics and Gynecology—Chairman, E. E. Montgomery, Pa.; Vice-Chairman, Bedford Brown, Va.; Secretary, F. H. Martin, Ill.

The following resolution was unanimously adopted by the Section:

Resolved, That in the future the papers to be presented to this Section shall be limited to forty, and the chairman shall have full discretionary power in selecting such papers from those offering.

Dr. Thos. F. Wood, N. C., read the report of the Committee on the Centenary of Vaccination. (Report not received.)

On motion of Dr. J. F. Hibberd, Ind., it was

Resolved, That the Committee on the Jenner Centennial be continued for another year, and that at the next annual meeting of this Association the Committee report, naming suitable persons, known to be students of vaccinology, to form a standing committee to whom the whole subject be entrusted, and that the 15th day of May, 1896, be chosen and set apart as the day upon which we will celebrate the centennial of the discovery of vaccination.

Resolved, Further, that the meeting of this Association for 1896 be so arranged as to include the above date.

REPORT OF COMMITTEE ON PRESIDENT'S ADDRESS.

Dr. Culbertson, Ohio, presented the following:

Your Committee, to whom was referred the suggestions contained in the President's Address, beg leave to recommend the adoption of the following resolutions:

Resolved, That all business matters of the Association be referred without discussion or comment to an execu-

tive committee composed of two members to be appointed by each State Society in affiliation with this Association, who shall carefully consider and recommend such action thereon as they may deem most advisable.

Resolved, That the time of meeting of the Sections be from 9 A.M. to 12 M., and from 2 to 6 P.M., and that the time of the general sessions shall begin at 12 M. and continue until adjournment.

Signed, P. O. HOOPER,
J. C. CULBERTSON,
LEARTUS CONNOR,
HENRY O. MARCY,
HAROLD N. MOYER.

This was laid over as an amendment to the By-laws.

Dr. A. L. Gihon offered an amendment to the By-laws, making Wednesday the day for the delivery of the President's address.

THE INCORPORATION OF THE ASSOCIATION.

Dr. Harvey Reed, Ohio, offered the following:

WHEREAS, The American Medical Association has never been incorporated, and has in consequence no legal existence, therefore be it

Resolved, That a committee of seven be appointed by the President to proceed at once to procure its incorporation; and that said committee of incorporation be and are hereby instructed to name the Judicial Council of this Association for the Trustees of said incorporation.

A motion of Dr. J. E. Woodbridge, Ohio, to lay this on the table was negatived.

After much discussion, on motion of Dr. J. F. Hibberd, Ind., the motion was amended to read that the committee be appointed to devise a plan for the incorporation of the Association and report their action at the next annual meeting.

The question then being on the amendment as amended, Dr. Hibberd offered as a substitute for all that was before the house,

That a committee of seven be appointed to devise a plan of incorporation and report next year.

This was unanimously adopted.

The Permanent Secretary announced the presence in the house of Mr. W. Taylor, President of the American Pharmaceutical Association, and Prof. Joseph Remington, a delegation from that body, and mentioned the fact that Mr. Taylor had been engaged in work on the Pharmacopoeia for forty years. On motion these gentlemen were invited to seats on the platform.

Messrs. Taylor and Remington were received and accorded seats, and Prof. Remington earnestly thanked the Association for their courtesy and for the formation of the Section of Materia Medica and Pharmacy, as follows:

WHEREAS, The American Medical Association has organized a Section of Materia Medica and Pharmacy, and has invited twenty-five members of the American Pharmaceutical Association to meet with them and discuss questions of mutual interest. The Section having been duly organized, and numerous papers having been read and subjects considered, to the satisfaction and benefit of the members attending, it is therefore

Resolved, That the delegation from the American Pharmaceutical Association express their high sense of appreciation of the action of the American Medical Associa-

tion, and sincerely trust that the movement which has been inaugurated so auspiciously may redound to the advantage of the professions of medicine and pharmacy.

The Permanent Secretary, in the absence of Dr. W. L. Schenck, Kans., arose to read the *Address on State Medicine*. On motion of Dr. J. G. Kiernan, Illinois, it was read by title.

Dr. F. Woodbury, Pennsylvania, from the Section of *Materia Medica and Pharmacy*, offered the following:

Resolved, That the Government of the United States be memorialized by the American Medical Association in favor of the plan proposed by Dr. F. E. Stewart, whereby the valuable work of the laboratories of the Army, Navy, Marine-Hospital Service, Smithsonian Institution, Customs Service, Agricultural Department and other departments of the public service, *in the line of identification and analysis of drugs* may be facilitated and made of more general utility, by the publication of their results, so that the information thus gathered may be disseminated for the general benefit of the professions of medicine and pharmacy.

On motion this was adopted.

Dr. Wm. H. German, Illinois, offered the following:

Resolved, That a committee of three be appointed by the President, to report at the next general session of this Association, to draft a memorial for presentation to the Congress of the United States, in accordance with the suggestion of the Hon. John C. Ross in his Address of Welcome to this Association, asking that the common law be so amended that confidential communications between physician and patient shall be respected in the same manner as those between attorney and client.

On motion of Dr. Kiernan this was adopted.

The report of the Section on State Medicine, by Dr. Benjamin Lee, Pennsylvania, was read by the Permanent Secretary and accepted.

A paper by Dr. W. W. Parker, Virginia, on *Intelligence in Man and Animals*, was offered and read by title.

The Permanent Secretary announced the officers of the Sections for next year as follows:

Practice of Medicine—Chairman, ———; Secretary, ———

Surgery and Anatomy—Chairman, J. McF. Gaston, Georgia; Vice Chairman, M. Price, Pennsylvania; Secretary, W. F. Mann, Michigan.

Medical Jurisprudence and Neurology—Chairman, H. N. Moyer, Illinois; Vice-Chairman, J. E. Emerson, Michigan; Secretary, G. D. Strawbridge, Pennsylvania.

Obstetrics and Diseases of Women—Chairman, ———; Secretary, ———

Diseases of Children—Chairman, E. F. Brush, New York; Secretary, B. A. Waddington, New Jersey.

Dermatology and Syphilography—Chairman, L. D. Bulkley, New York; Secretary, J. C. McGuire, District of Columbia.

Oral and Dental Surgery—Chairman, J. Paft, Ohio; Secretary, E. S. Talbot, Illinois.

Otology and Laryngology—Chairman, ———; Secretary, ———

Ophthalmology—Chairman, ———; Secretary, ———

Materia Medica and Pharmacy—Chairman, Frank Woodbury, Pennsylvania; Secretary, W. L. Whippley, Missouri.

State Medicine—Chairman, Benjamin Lee, Pennsylvania; Secretary, L. F. Flick, Pennsylvania.
Physiology and Dietetics—Chairman, C. H. A. Kleinschmidt, District of Columbia; Secretary, ———

A motion to amend the title of the Section of Neurology, etc., by adding Psychiatry, was laid on the table by a large vote.

Committee on Medical Aid Association (Resolution by Dr. Horner), Frederick Horner, U. S. N.; Benjamin Lee, Pennsylvania; John H. Hollister, Illinois.

The report of the Judicial Council having been asked for Dr. N. S. Davis, explained that time was needed to investigate the matters referred, and the report would be offered at next session.

Dr. J. N. Love, Missouri, moved that it be the sense of this Association that Dr. W. W. Potter should have no hesitation in serving on the Board of Trustees.

The President decided this not in order.

As several members had applied to be appointed delegates abroad, the President, after some remarks on the subject, announced that he would appoint them to all save the British Medical Association.

After some discussion, and a motion that no appointments be made to the British Medical Association, on motion the whole subject was laid on the table.

On motion of Dr. J. E. Woodbridge, Ohio, the President and Permanent Secretary were authorized as usual to issue credentials abroad to such societies as were deemed proper.

The Permanent Secretary read the following:

PROCTOR, VT., May 6, 1891.

DR. N. S. LINCOLN, Washington, D. C.

My Dear Sir:—Am very sorry not to be in Washington this week to be of any help in my power in entertaining the medical society, but I find it impossible to be with you. Very truly yours,

REDFIELD PROCTOR.

On motion of Dr. W. K. Sheddon, Tennessee, it was

Resolved, That the thanks of the Association were tendered to the local committee of arrangements, and the other physicians and citizens of Washington, to the trustees of the different museums and art galleries, and to the hotels and railroads for their many kindnesses and favors shown to the members during their stay here, and that this motion be passed by a rising vote.

The vote was adopted by the entire assemblage rising.

Dr. J. E. Woodbridge, Ohio, said:

"It has been my good fortune to have attended many meetings of the American Medical Association, but never before have I seen the As-

sociation so honorably and agreeably, yet so firmly and well presided over as at the present meeting, and the duties of the President and of the Permanent Secretary so satisfactorily performed, therefore I move that the thanks of this Association are due and are hereby tendered to Dr. Briggs, of Tennessee and Dr. Atkinson, of Pennsylvania." Carried unanimously.

The President then introduced Dr. H. O. Marcy, Massachusetts, the President-elect, who accepted the duties of his office in a speech alluding to the venerable ex-presidents, Drs. Bowditch, and Storer, both of Boston, Mass., in terms of profound respect and regret that they had not been with the Association this year.

On motion of Dr. F. Woodbury, Pennsylvania, it was

Resolved, That the Permanent Secretary be directed to send telegrams to our venerable ex-presidents, Drs. Henry L. Bowditch and D. Humphreys Storer, of Boston, expressing the high esteem in which we continue to hold their former labors in the American Medical Association, and of our continued personal regard; and greatly regret that they were unable to be present with us at the present meeting.

The retiring President, Dr. W. T. Briggs, then alluded to the pleasure he had enjoyed in presiding over the meeting, thanking the members for their support and bade them good bye and God speed.

On motion of Dr. N. S. Davis, the Association then adjourned to meet in Detroit, Mich., on the 1st Tuesday of June, 1892.

WILLIAM B. ATKINSON,
Permanent Secretary.

LIBRARIAN'S REPORT.

Mr. President:—I have the honor to present the catalogue of additions to the Library of the Association during my term as Librarian of the American Medical Association.

This report shows the addition of 45 Periodicals, 24 Reports of various kinds, 14 Society Transactions, 5 Hospital Reports, 16 Dissertations and Papers, and 8 College Announcements.

I would suggest, on account of the crowded condition of the library—one of the towers of the Smithsonian Institute Building—that other quarters be selected for its habitat. The tower is now overcrowded, the shelving space all used up, and the new material must be piled, layer over layer, on the floors, where it is not only inaccessible, but where no one cares to seek it. I would also suggest that the subscription to the *Index Medicus* for the current year be continued, and the sum of \$10 be appropriated for that purpose.

CATALOGUE OF ADDITIONS TO THE LIBRARY OF THE AMERICAN MEDICAL ASSOCIATION, BY DONATION, EXCHANGE AND SUBSCRIPTION, FROM MAY 1, 1890, TO MAY 1, 1891.

REPORTS.

Consular Reports (U. S.), Nos. 114-125.

SOCIETY PROCEEDINGS.

Fort Wayne (Ind.) Academy of Medicine.
Regular Session, March 30, 1891.

DR. L. K. McCULLOUGH read the paper of the evening, entitled

SHURLY'S TREATMENT.

The essayist gave an outline of the present treatment of Shurly and Gibbes, and appended the history of four cases. The essayist suggests that inasmuch as chlorine gas is irrespirable, producing spasmodic closure of the glottis, it would

not penetrate the bronchial tubes of medium calibre, to say nothing of the air cells; that if chlorine gas is necessary to prevent coagulation and the formation of the ptomaine toxalbumin, it might be gotten into the tissues through rectal insufflation.

Case 1.—Mrs. C., æt. 33 years, since birth of last child, eighteen months ago, has been in failing health. January 3, is in last stage of phthisis. Daily injections of iodine for ten days, and five more on alternate days; inhalation of chlorine gas caused so much distress that it was abandoned. Patient was better subjectively, objectively no improvement. Now failing rapidly, and will soon die.

Case 2.—I. A., cigar maker, æt. 27. Family history good. For past fourteen months patient thinks he has been out of health. Has had three separate hæmorrhages; slight cough; general condition fair; appetite good. Dec. 29, right lung no abnormal signs; on left side infra-clavicular space gave tubular breathing; dulness on percussion and crackling râles on deep inspiration. Temp. 99.5; no expectoration. Iodine injections daily, gr. $\frac{3}{4}$, increased to gr. $\frac{5}{4}$, given for fifteen days. No chlorine inhalation. Beechwood creosote gr. $\frac{1}{2}$, t.i.d. Hypophosphites and malt were used. Patient has gained eight pounds in weight. Coughs scarcely any, temp. normal, physical signs improved, but probably due to disappearance of local congestion.

Case 3.—Æt. 25; incipient stage; treatment two weeks; no change.

Case 4.—J. P., æt. 38; tubercular history; husky voice; congestion of larynx for past two years; sputum shows bacilli. Lost a brother recently from phthisis. Expectoration very profuse. Since treatment expectoration has ceased, till at present time can not get enough for examination. Chlorine gas inhalations not used. Chloride gold was used for a time but was discontinued on account of pain and nodulation at site of puncture. Arynoid ragged; no abscess has followed injections; rubbing relieves pain of puncture.

DR. PROEGLER said he was acquainted with case 4, and the tubercular history is undoubted. Since six weeks patient has improved very rapidly. Gold injections makes patient feel very tired. At present there is no expectoration; no night-sweats; appetite improving, and now walks several blocks where before was unable to go out. Right lung has cleared up and râles not appreciable. Patient had continued beechwood, creosote, hypophosphites and malt.

DR. WHEBY: It would be difficult to say that results were due entirely to injections. Am better impressed with Shurly's treatment than with Koch's because it produces no reaction.

DR. SCHILLING: Have had no experience with the Shurly method.

DR. WHEELOCK: Am interested indirectly in the treatment on account of the possibility of curing those secondary tubercular affections of the eye found in patients with phthisical antecedents.

DR. McCASKEY: Have had some experience with iodine injections, but not enough to base a definite opinion upon. Maximum dose of iodine as used by essayist seems small. I think it may be safely carried to 1 gr. My injections have been followed by pain, hence I use sol. cocaine. The treatment shows that irritating injections may be used with perfect safety and without danger of suppuration.

DR. PROEGLER: I think there is a psychical element in the injections, and that after the weary routine of reconstructives the injections act upon the mind as well as physically.

DR. McCULLOUGH: Am not prepared to offer any opinion as to the real value of the treatment, and can not till more statistics have been brought forward.

BOOK REVIEWS.

DIE WIRKSAMKEIT DES KOCHSCHEN HEILMITTELS GEGEN TUBERCULOSE.

For some years it has been the custom of the minister of medical affairs in Germany to issue a year book, in which are published the official reports of the directors of different clinics. This volume forms a supplement for the regular volume and contains thirty-three reports of the results obtained with Koch's method up to the close of December, 1890, or about eight weeks' experience—too short a time to come to any conclusion as to the permanent value of the method. The majority of opinions are more or less favorable as to the diagnostic and therapeutic value of the method, but in many instances an opinion is reserved or guardedly expressed. Of 1,010 patients with tuberculosis of the internal organs who were subjected to the treatment, only 13 are said to have recovered, 305 were benefited, 586 remained stationary, and 46 died. Of the 13 cases reported cured, 10 were in the first stage, and 267 of those reported improved were either in the first stage, or else the disease had made but little progress.

PIPERAZIDINE AS A SOLVENT FOR URIC ACID.

It is stated in a German pharmaceutical journal that piperazidine dissolves uric acid more readily than any other substance of a basic nature. Urate of lithia requires 368 times its own weight of water to dissolve it, but urate of piperazidine dissolves in fifty times its weight of water. It may therefore be expected that this drug will become a fashionable, let us hope, too, an efficient remedy in gout and allied diseases.

NECROLOGY.

Necrology Report for the State of Connecticut.

Hartford County.—The following members of the State Medical Society have died during the year: Geo. E. Markham, East Hartford; R. B. Watkins, So. Manchester; J. S. Butler, Hartford; S. W. Rockwell, So. Windsor; Casper Barstowe, E. Hartford.

Tolland County.—Joel Addington Warren, M.D., born at Irisburgh, Vt., February 15, 1834; died at Ellington Corner, December 25, 1890. Graduated from the Albany, N. Y., Medical School in 1859.

Fairfield County.—James R. Cumming, M.D., of Bridgeport.

New London County.—Robert A. Mainwaring, M.D., of New London; died September 1, 1890.

Respectfully submitted,

W. A. M. WAINWRIGHT, M.D.

Sidney Allan Fox, M.D.

The following memoir of the late Dr. Sidney Allan Fox, member of the Kings County Medical Association, was read at the stated meeting, March 10, 1891:

Dr. Sidney Allan Fox died of pneumonia, at his residence, 22 Cambridge Place, Brooklyn, on Saturday, January 10, 1891, aged 34 years, 6 mos. and 26 days. He was born at Mount Sterling, Ky., graduated from the University of Kentucky, and pursued the study of medicine at Bellevue Hospital Medical College, New York City, receiving the diploma of that institution in 1880.

He served one year each as interne in the Charity Hospital and the New York Hospital for the Relief of Ruptured and Crippled, and came to Brooklyn in 1882. He was Surgeon to the Brooklyn Elevated R. R., and Surgeon in Chief to the Brooklyn Dispensary for the treatment of the Diseases of the Nose, Throat and Lungs. He joined this Association in January, 1888, and always took an active interest in its proceedings. He was especially interested in the diseases of the respiratory system. By his death the Association has lost a valuable member, and the profession one of the ablest of its younger men. The members of this Association unite in expressing their profound regret at the death of Dr. Fox, and tender to the bereaved family their sincere sympathy.

WM. WATERWORTH,

F. C. RAYNOR,

Committee.

Richard Gundry, M.D.

Dr. Richard Gundry, a member of the faculty of the Baltimore College of Physicians and Surgeons, died at Spring Grove, Md., on April 23, 1891. He was born in England, near London, about sixty-two years ago, the son of a talented clergyman. In 1845 he went to Canada, and soon afterwards began his medical studies. He graduated five years later from the medical department of Harvard University. He began medical practice at Rochester, N. Y., but in 1854 removed to Columbus, O., to become an assistant physician in the Lunatic Asylum. In 1857 he went to Dayton to occupy a similar position, and became Superintendent of that institution in 1862. He was afterwards identified with the care of the insane at Athens, O., and again at Columbus, and later at Catonsville, Md. Dr. Gundry superintended the building of two or more large asylums, and was the author of numerous reports on improving the care of the insane. After his removal to the vicinity of Baltimore, he accepted the chair of materia medica, therapeutics and mental diseases in the college above named. His final illness was due to Bright's disease.

MISCELLANY.

IN OUR last issue the name of Dr. J. C. LeGrand, of Alabama, should appear instead of Lagrange, as member of the Nominating Committee.

NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.—At the meeting of the Directors of the New York Post-Graduate Medical School and Hospital, H. J. Boldt, M.D., was made Professor of Diseases of Women, William James Morton, M.D., Professor of Electro-Therapeutics and Aug. Caille, M.D., Professor of Diseases of Children. Clarence C. Rice, Secretary.

SOUTH DAKOTA STATE MEDICAL SOCIETY.—The tenth annual meeting of the South Dakota State Medical Society will be held at Chamberlain, South Dakota, on Wednesday, Thursday and Friday, June 10, 11 and 12, 1891. Members of the medical profession are cordially invited to attend.

Program.—Business sessions will be held at Masonic Hall, Wednesday, June 10, 1891, 8 P.M. Call to order. Prayer, Rev. D. B. Nichols, M.D. Address of Welcome, Mayor John T. Anderson. Response, W. E. Duncan, M.D. President's Annual Address, J. W. Freeman, M.D. Report of Committee of Arrangements.

Thursday, A.M. Report of Censors and Admission of New Members. Appointment of Committees. Report of Secretary. Report of Treasurer. Report of Standing Committees. Reports of Delegates to American Medical Association and other Societies.

Sessions.—Report on Medicine, Dr. I. R. Spooner, Chairman. Report on Medicine, Dr. C. J. Cummings, Secretary.

Report on Surgery, Dr. G. W. Moody, Chairman. Report on Surgery, Dr. S. J. Coyne, Secretary.

Report on Obstetrics and Diseases of Women, Dr. H. VanBuskirk, Chairman. Report on Obstetrics and Diseases of Women, Dr. A. H. Bowman, Secretary.

Report on Nervous Diseases, Dr. S. B. McGlumphy, Chairman. Report on Nervous Diseases, Dr. H. H. Stoner, Secretary.

Report on Hygiene, Dr. S. A. Brown, Chairman. Report on Hygiene, Dr. J. B. Graham, Secretary.

Thursday, P.M. Report on Endemic Diseases, Dr. Fred. Treon, Chairman. Report on Endemic Diseases, Dr. R. E. Buchanan, Secretary.

Report on Microscopy, Dr. H. S. Sevey, Chairman. Report on Microscopy, Dr. G. E. Martin, Secretary.

Report on Diseases of Children, Dr. F. B. Bullard, Chairman. Report on Diseases of Children, Dr. F. P. Smith, Secretary.

Report on Diseases of Eye and Ear, Dr. A. Shaw, Chairman. Report on Diseases of Eye and Ear, Dr. W. J. Nolan, Secretary.

Report on Dermatology and Venereal Diseases, Dr. M. Ware, Chairman. Report on Dermatology and Venereal Diseases, Dr. R. T. Dott, Secretary.

Report on Vital Statistics, Dr. F. A. Spafford, Chairman. Report on Vital Statistics, Dr. O. O. Sawyer, Secretary.

Report on State Legislation, Dr. W. M. Kaul, Chairman. Report on State Legislation, Dr. A. H. Tufts, Secretary.

Papers.—Laceration of Cervix Uteri, Trachelorrhaphy, and relation to Conception and Pregnancy, Dr. J. S. Johnson.

Ophthalmology and its Relation to General Practice, Dr. A. Shaw.

Diseases of Children, Dr. F. B. Smith.

Also papers by Drs. I. R. Spooner, F. A. Spafford, S. J. Coyne, W. J. Nolan, O. W. Phelps, G. W. Moody, J.

B. Graham, S. B. McGlumphy. Volunteer Papers and Report of Cases.

Thursday Evening. Unfinished Business. Report of the Nominating Committee. Election of Officers. Appointment of Committees and Sections for Ensuing Year. Reading of the Minutes. Adjournment.

Officers.—President, Dr. J. W. Freeman; Vice-President, Dr. M. Ware; Second Vice-President, Dr. A. H. Tufts; Secretary, Dr. R. C. Warner; Assistant Secretary, Dr. S. L. Halverson; Treasurer, Dr. J. C. Morgan. **Trustees.**—Dr. F. Andros, Dr. S. B. McGlumphy, and Dr. F. B. Bullard.

Committee of Arrangement.—Dr. R. H. Goodrich, Dr. S. L. Halverson, Dr. May, Dr. Cook, Dr. Lloyd.

Notes.—Article III of the Constitution. Section 4: "Permanent members shall be regular practitioners of medicine in the State, shall be graduates of a medical college in good standing, shall be members of the local society where they reside where such society exists."

"Every application shall be accompanied by the sum of \$3.00 membership fee."

The society has largely increased as to membership and attendance the past few years, and the interest in our society work has increased in proportion. It is wished that all the physicians in the State will join in the good work.

The railroads refuse reduced rates so that each one will probably find it the best to buy round trip tickets.

The hotels—"Hotel Taft," "Wright House," "Brule House," and "Merchants House,"—kindly make a rate of \$1.50 per day.

Capt. H. J. King extends an invitation to the society for a pleasure trip on the Missouri river sometime during the meeting.

The committee on arrangements promise all a good time.

THE GOLDEN BELT IN THE CAPITAL CITY OF KANSAS.

—The Golden Belt District Medical Society of Kansas convened in regular quarterly (annual) session in the club rooms in the National Hotel, in Topeka, April 9, in response to an invitation by the physicians of the capital city, who entertained the visitors royally and attended the sessions in a body. The attendance was very large and the programme unusually interesting, especially so by virtue of the liberal discussions of the papers read, the cases reported, and the difficult operation performed by Dr. Emory Lauphear, of Kansas City, Mo., who exhibited great skill as operating surgeon in demonstrating upon a dog recent improvements in intestinal surgery. The programme carried out was as follows:

Dr. J. H. Garvey, of Wisley, "Chronic Cystitis with Report of Cases."

Dr. C. H. Guibor, of Topeka, "Report of Cases of Adenoid Growths in the Throat."

Dr. Emory Lauphear, of Kansas City, Mo., "Some Recent Improvements in Intestinal Surgery, with Demonstrations upon a Dog."

Dr. H. Cordier, of McPherson, "Phimosis, Local and Remote Results."

Dr. Chas. W. Adams, of Kansas City, "Peri-Uterine Inflammation."

Dr. P. Daugherty, of Junction City, President, "Annual Address."

Dr. L. H. Berger, of Kansas City, "Use of Obstetric Forceps."

Dr. Hal. Foster, of Kansas City, "Report of a Case of Submucous Hæmorrhage of the Larynx."

This being the annual meeting, officers for the ensuing year were elected as follows:

President, Dr. Wm. B. Dewees, of Salina.

First Vice-President, Dr. Z. T. Harvey, of Council Grove.

Second Vice-President, Dr. T. N. Gunn, of Chapman.

Secretary, Dr. F. B. Browne, of Salina.

Treasurer, Dr. E. Kauffman, of Abilene.

The new president was introduced formally by the retiring president who, upon taking the chair, made a brief address in which he thanked the members for the honor conferred upon him. A vote of thanks was tendered the retiring president. It was agreed by vote to accept the invitation of the retiring president to hold the next meeting at Junction City in July. The Golden Belt is one of the three most prosperous societies in the State of Kansas. The attendance at this meeting numbered over seventy, and included a large number of the leading practitioners and teachers of medicine in Kansas, and five from Kansas City, Mo. The meeting was the most interesting and profitable one in the history of the Society.

NEW YORK STATE MEDICAL ASSOCIATION, FIFTH DISTRICT BRANCH.—The seventh annual meeting of the Fifth District Branch will be held in Wurzel's Building, 315 Washington street (over the Post Office), Brooklyn, on Tuesday, May 26, 1891.

The morning session will be called to order at 11 A.M., and will be devoted to the

President's Address, "Opiales in the Treatment of Acute Peritonitis."

Business of the Branch.

Biographical sketches of the late Dr. James Bathgate, by John Shady, M.D.; Dr. W. N. Blakeman, by Mr. A. N. Blakeman; Dr. John P. Garrish, by W. T. White, M.D. Scientific papers on

"Cathartics in the Treatment of Acute Peritonitis," by A. Palmer Dudley, M.D.

"The Treatment of Hydrocele by Carbolic Injection versus the Radical Operation," by Samuel E. Milliken, M.D.

Adjournment at 1 P.M. for lunch.

The afternoon session will be called to order at 2 P.M., and will be devoted to the remaining scientific papers:

"Scarlatinal Diphtheritis and its Treatment," by E. G. Rave, M.D.

"Practical Results of the Operation for Lacerated Cervix Uteri," by H. W. Mitchell, M.D.

"Objections to the Ordinary Axis-traction Instruments, also the Advantages of the Use of the Anticraniotomy Forceps over Version in Pelvic Deformities," by T. J. McGillicuddy, M.D.

"A Case of Obstinate Neuralgia Following Fracture Relieved by Operation," by Reginald H. Sayre, M.D.

"Acute Prostatitis and Prostatic Abscess," by William R. Ballou, M.D.

The Nominating Committee will then make its report of members of the Executive Committee for the ensuing year.

The present accumulation of interest from the Permanent Fund will enable the Branch to furnish lunch to all in attendance without charge.

LETTERS RECEIVED.

Albany, N. Y., Dr. A. Marsh.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from May 9, 1891, to May 15, 1891.

Lieut. Col. James C. McKee, Surgeon, having been found incapacitated for active service by an Army Retiring Board, is, by direction of the Acting Secretary of War, granted leave of absence until further orders on account of disability. Par. 11, S. O. 106, A. G. O., Washington, May 9, 1891.

Capt. Henry P. Birmingham, Asst. Surgeon, the extension of the ordinary leave of absence granted in S. O. 81, A. G. O., April 10, 1891, from this office, is changed to leave of absence on account of sickness, to date from May 1, 1891. By direction of the Acting Secretary of War. Par. 4, S. O. 108, A. G. O., May 12, 1891.

Lieut. Col. Dallas Bache, Surgeon, is relieved from duty as a member of the Army Medical Examining Board, New York City, and will return to his proper station, Omaha, Neb., and resume his duties as Medical Director, Dept. of the Platte. By direction of the Acting Secretary of War. Par. 5, S. O. 108, A. G. O., May 12, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Two Weeks Ending May 10, 1891.

P. A. Surgeon W. H. Rush, detached from "Saratoaga" and prepare for sea.

P. A. Surgeon S. W. Atlee, detached from Navy Yard, League Island, and to "Saratoaga."

Asst. Surgeon C. De W. Brownell, ordered to Navy Yard, League Island, Pa.

Surgeon T. H. Streets, detached from Naval Examining Board and prepare for sea.

Surgeon B. S. Mackie, considered as member of Naval Examining Board.

P. A. Surgeon L. W. Curtis, detached from Naval Academy and to the Practice ship "Conellation."

Asst. Surgeon Philip Leach, ordered to U. S. Practice ship "Conellation" revoked.

Surgeon G. P. Bradley, detached from "Mohican" and placed on waiting order.

Medical Inspector T. C. Walton, Surgeon Geo. A. Bright, and P. A. Surgeon J. M. Steele, ordered to Naval Academy to examine applicants physically for admission.

Surgeon S. H. Dickson, ordered to the "Conellation."

P. A. Surgeon W. H. Rush, detached from "Saratoaga," and await duty to sea.

P. A. Surgeon L. W. Atlee, detached from Navy Yard, League Island, and to the "Saratoaga."

Asst. Surgeon C. D. W. Brownell, ordered to Navy Yard, League Island.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Three Weeks Ending May 9, 1891.

Surgeon H. W. Austin, detailed as chairman of Board for physical examination of candidates for appointment, Revenue Marine Service. May 9, 1891.

P. A. Surgeon P. M. Carrington, granted leave of absence for twenty-three days. May 5, 1891.

P. A. Surgeon W. D. Bratton, when relieved at Portland, Ore., to proceed to Chicago for duty. May 5, 1891.

P. A. Surgeon G. M. Magruder, detailed as recorder of Board for physical examination of candidates for appointment, Revenue Marine Service. May 9, 1891.

Asst. Surgeon A. Condit, relieved from duty at Chicago, Ill.; ordered to Portland, Ore. May 9, 1891.

Asst. Surgeon H. D. Geddings, to proceed to New York on special duty. May 9, 1891.

Asst. Surgeon B. W. Brown, to report to commanding officer, Revenue str. "Rush" on the 14th inst. May 7, 1891.

Surgeon H. W. Austin, detailed as member of Board of Examiners, Marine-Hospital Service, April 21, 1891. Detailed as chairman of Board for physical examination of officers and candidates, Revenue Marine Service, April 29, 1891.

Surgeon John Godfrey, detail as member of Board of Examiners revoked. April 21, 1891.

Surgeon Fairfax Irwin, detailed as recorder of Board for physical examination of officers and candidates, Revenue Marine Service. April 29, 1891.

P. A. Surgeon P. M. Carrington, to proceed to Ferdinandina and examine candidates, as Inspector. May 1, 1891.

Asst. Surgeon W. G. Stimpson, when relieved, to proceed to Savannah, Ga., for temporary duty. May 2, 1891.

omitted from Previous List.
Asst. Surgeon B. W. Brown, detailed as medical officer, Revenue str. "Rush," during summer cruise. April 14, 1891.

ORIGINAL ARTICLES.

MEDICAL PROGRESS.

Read by Title in the Section of Medicine and Physiology, at the Forty-Second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY C. R. EARLEY, M.D.,
OF RIDGWAY, PA.

My time is so limited that I can only make a very slight review of the practice of medicine, showing the progress made during so many years.

The present time can boast of great progress; yet we have much to regret as to the failures to come up to the standard of olden times in many respects. We should look well to this.

Medicine has its history, its philosophy, its politics, its literature, of which the world at large knows nothing. It has its arts and occupations; it has its organizations and institutions, and dissections, not always amenable to logic or to the learning of the schools. In ethics, traditions and superstitions it dates anterior to the Church. Being in use before the civil law, is it any wonder that the members of our profession, drawn together by such ties, should unite as a brotherhood? Such has ever been their course. The Druid of early Gaul and Britain, the Asclepiades of Greece, the Priests of Egypt, the Lamas of Central Asia, the Fraternities of the Middle Ages, and up to this time medical societies and colleges in our own and other countries devoted to the healing art, are the proof of this. Wherever freedom has existed, or tyranny would permit, organization and development have been the rule of our profession.

With these facts before us our duty is plain. Continue this good work and improve every day, and show ours to be a progressive profession. Let us look back for ages and review its history up to our time, that we may the better understand, and may know how far we have advanced, and to what we owe our progress. The labor before us is, how we can best elevate the profession for those who are to follow.

Among the early Egyptians were a large and influential body of priests, who received about one third of the income of the nation. There were several orders of them. A majority of them were skilled in medicine, and, as many supposed,

practiced gratuitously among the people. (See Schultze, page 24, from Diodorus.)

"Each physician applies himself to one disease and not more." Every place was full of physicians; some for the eyes, others for the head, some for the teeth and others for internal diseases—what we call specialists. The embalmers were also of this class, and their skill and standing are generally respected to this day. The skill of the Egyptian priests or doctors made them very popular, not only among the Egyptians, but the rulers of the surrounding nations called for them. Cyrus sent for the ablest oculist of Egypt. We learn from Aristotle that the practice of the Egyptian priests was in conformity with a law prescribed, yet the physicians were allowed to alter the mode of cure, which the law prescribed to them, after the fourth day, but if they did sooner they acted at their own peril.

The youth who were destined for the profession, if not the sons of the initiated, were not allowed to begin until after the completion of their preparatory education, from their seventeenth to their twentieth year. But the sons of the physicians began earlier, and with both the course of training continued to about their twenty-fifth year. The admission or initiation of those who had passed the preliminary examination consisted of the three grades.

The ceremony of the first grade was called illumination, or the study of theories, logic and philosophical or abstract principles and rites. The second grade was styled inspection, which included the looking on or practical studies, or the examination of diseases in the houses and at the bedside. The third grade, which was the end of their study, and the design of the other two, was called the binding of the head, or coronation. The binding of the head was equivalent to what we call graduation, and never took place before the completion of the fifth year. It will be remembered that not all presenting themselves for admission as students were accepted, as a thorough examination was made as to their preliminary qualifications and education, their general character, moral and intellectual. They must be perfectly free from all physical deformities, and have a clear and good voice and no impediment of speech.

We are informed by Hippocrates, in reference to his profession, that "Things which are sacred are to be imparted only to sacred persons," and that "It is unlawful to impart them to the profane until after their initiation into the mysteries of the science." With reference to purification, or the training which should precede illumination, he says: "Whoever is to acquire a competent knowledge of medicine ought to possess the following advantages: A natural disposition, a favorable position for study, early tuition, love of labor and leisure." Writing to his son, the author of the Hippocratic Letters says: "Give due attention, my son, to geometry and arithmetic, for such studies will not only render your life illustrious and useful to your fellow beings, but your mind more acute and perspicacious in arriving at fruitful results in everything pertaining to your art."

The candidate having passed the first ordeal of preparation, and commencing the ceremonies of illumination, was obliged to subscribe to the oath, which was a formula analogous to that which was enjoined among the Pythagoreans, and was in the following words: "I swear by Apollo, the Physician, by Esculapius, by Hygeia, by Panacea and all the gods and goddesses, that according to my ability and judgment, I will keep this, my oath and stipulation, to reckon him who teaches me this art equally dear to me as my parents, to share my substance with him and to relieve his necessities if required; to look upon his offspring on the same footing as my own brothers, and to teach them this art, if they shall wish to learn it, without fee or stipulation, and by precept, lecture and every other mode of instruction. I will impart a knowledge of this to my own sons, to those of my teachers and to my disciples, bound by stipulation and oath according to the law of medicine, but to none others. I will follow that system of regimen, which according to my ability and judgment, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to any one, if asked, nor suggest any such counsel; and in like manner I will not give a woman a pessary to produce an abortion. With purity and holiness I will pass my life and practice my art. I will not cut persons laboring under a stone, but will leave this to be done by men who are practitioners of this work. In whatsoever house I enter I will go into them for the benefit of the sick, and will abstain from any seduction of females and males, of freemen and slaves. Whatever in connection with it I see or hear I will not divulge, as reckoning that all such should be kept a secret. While I continue to keep this oath inviolate, may it be granted to me to enjoy life and the practice of my art, respected by all men and at all times; but should

I trespass and violate this oath, may the reverse be my lot." See Adam's Hippocrates, Vol. II, page 779.

The course of education among the Asclepiades was in conformity with the national habits. After subscribing to this oath the pupil was allowed to proceed to the business of illumination, which consisted of the committing to memory certain traditions and precepts, in listening to his instructor, in the description and management of diseases within the temple or at the bedside of the sick, and combining with the knowledge thus obtained a general acquaintance with the rules of health. Next in order came the business of inspection. It immediately preceded coronation; this had relation to practical subjects, probably the treatment of diseases under the immediate supervision of the instructor. The ceremony of coronation took place at the completion of the term of study, as the ceremony of graduation takes place in our colleges at the present time.

In those days medicine was principally taught orally or by tradition and example, therefore the requirements could not have been very extensive. This main study of the treatment of acute diseases was the regulating of the diet, etc. Epidemic diseases were looked upon as of divine dispensation, with which they dare not interfere. A knowledge of the general rules of health and the influence of diet, exercise, climate and locality attracted much of their attention. Why should not the same attention be paid to the subject at this day?

In the management of injuries and external diseases they were but little behind those of the present day. Their remedial agents were the lancet, active cathartics, emetics and diuretics, cataplasms, ointments, escharotics and mechanical appliances. They had but little knowledge of anatomy and physiology; they did not interfere to any extent with chronic diseases.

Up to the days of Herodicus, one of the teachers of Hippocrates, he recommended in chronic diseases, exercise and regulated diet. This innovation was very unpopular. Plato upbraided him for his course, and declared that no attempt should be made to cure a thoroughly diseased system, and thus continue a long and miserable life to the man himself, as well as to his descendants. Asclepius did not think a man ought to be saved who could not live in the ordinary course, as he would be of no service to himself or the State.

Hippocrates can properly be called the father of the medical profession. He was born 460 years before the birth of Christ; was a few years older than Plato and younger than Socrates. He received his professional education under his father, Heraclides, at Asclepion of Cos, in his youth, at Athens and other places. He had the

instruction of the best teachers in science and philosophy.

Hippocrates in his book, "Air, Water and Places," inquires into the effect of particular exposures of the seasons and their vicissitudes; the influence of winds and properties of water. He refers to diseases prevalent in different places and during different times of the year. He calls attention to diet and exercise, showing how excess or deficiency in either may prove the cause of disease. If practitioners of this day would only follow this noble example and in all cases look well to the surroundings, location, diet, water used, drainage, cleanliness, as well as habits of the patients, it would do great good.

From the time of Hippocrates and immediate followers to the present time, a system of vacillations and changes in the theories and practice of medicine and surgery has been going on. Every day we see in print some new invention or theory suggested by members of the profession upon the diseases of the day. One cures all diseases by cathartics and emetics, claiming they are generated or produced by accumulations in the stomach and bowels; others that all diseases can be cured by heat, as one specialist of the kind advocated, giving as his reason, cold is death and heat is life, therefore as long as we can keep up the heat in the body the patient will live and must rally under its influences. Others, from the days of old to the present time, spring up to cure all diseases by bleeding, frequent and profuse depletion, and thus relieve congestion of different parts of the body from excess of blood. Aretæus, who had written eight books, was an advocate of the free use of hellebore as the great remedy for nearly all diseases. He also advocated the system of drastic medicines, and was among the first to recommend cantharides for blistering. Sydenham, born in 1624, differed greatly from his predecessors in their modes of treatment. He published his work entitled "Methodus Curandi Febris," in 1666, and it was he that first directed cool air and other antiphlogistics in the treatment of small-pox and eruptive fevers.

The Brunonian system was based on the views of Dr. John Brown, of Edinburgh. He arranged diseases under two divisions, sthenic and asthenic. He maintained that all agents operate on the body as stimuli, so we had only to increase or diminish the force of these according to circumstances. At the head of stimulants he places wine, brandy and opium, in the recommendation of which he is very liberal, and especially betrays his partiality to them by assertions contrary to universal experience. He found them in his own person the best preventative of gout, and is said to have prepared himself for his lectures by large doses of laudanum in whisky, and thus aroused himself to a degree of enthusiasm border-

ing on frenzy. The novelty and imposing simplicity of his doctrines procured him at first quite a numerous class, but being irregular in his attendance, and his habits of intemperance increasing, his class fell off by degrees, and he was at length so embarrassed as to be obliged to leave Edinburgh in 1786. He then settled in London, but met with little success, and in about two years after died. His opinions found many supporters in this country as well as in others, but they appear to have nearly fallen into deserved oblivion.

Berhaave's system was founded on the teaching of Dr. Herman Berhaave, who claimed to have selected his mode and manner of treating diseases from all systems and theories of those that preceded him, consequently he was called or styled an Eclectic.

As we have seen heretofore in this report, many of the old practitioners depended greatly upon depletory measures, particularly blood-letting. In most of the fevers of that day, as we are told by Rush and others, the sheet-anchor in the treatment was considered to be bleeding and drastic purgatives. This was kept up by one class and denounced by another, we may say, up to within the last forty or fifty years, since which time we have made great progress in omitting the use of the lancet. In scarlet fever bleeding was the practice of many of our most renowned physicians.

My own recollection of scarlet fever dates back to when I was a boy of seven years. Dr. Dana, a physician of high standing of Friendship, N. Y., and my father's family physician during a scourge of that disease, used the lancet freely in all cases, except two boys. The reason they were not bled the doctor and mother, in each instance, were unable to hold the two bad boys as they kicked, screeched and hollowed, arousing the neighbors, when the doctor said: "We will have to give it up; they will die but I cannot help it, we have done all we can." They recovered without any sequel while the other cases died; and here is one of the boys.

My first year's practice of medicine, in 1845, was in that village, and the old doctor referred to had retired from practice and spent much of his time in our office, and often repeated and laughed about his experience in the cases alluded to, stating that from that time he never used the lancet in scarlet fever.

In my first practice and experience it was considered malpractice to omit bleeding in pneumonia, pleurisy and diseases of like character. I shall never forget the last case I bled and the first I did not bleed in pneumonia. April 12, 1846, I was called to treat a young man with pneumonia, in Ridgway, Pa., and as I had been educated a physician in the state of New York and my first practice had been there also, where

the thumb lancet was always used, I took it to bleed the patient, but all the friends refused to have it used, calling it a "butcher knife," and, unlike my usual decided position, I stepped into a store and bought a spring lancet,—which was not considered a surgical instrument—and snapped it several times without effect on account of fear, as I could not guide it, but succeeded at last in bleeding the patient. About an hour after this I was called to see another young man with the same disease, which was prevalent at this time—as the raftmen had exposed themselves to the inclemency of the weather going down the river. I drew my lancet and met with the same positive protest against the use of it; so I took the spring lancet the second time and let it snap. The blade broke and flew across the room. I went to the door and threw the balance of it as far as I could, and said if he could not be bled with my instrument he might go without and die, as I was not responsible.

Under a treatment of small doses of ipecac and the solution of antimony tartrazum, and free bathing with salt water, with thorough friction of the body, three times a day, in two and one-half days my patient expectorated easily and freely, the surface was generally moist, and in five days was about his room, and in a few days well; while the one whom I bled, equally as stout and robust a young woodsman, in six weeks began to walk out a little on pleasant days. From that time to the present I have never resorted to bleeding in pneumonia, nor in any case save apoplexy or puerperal convulsions, or where immediate danger required it.

In 1793-94 Dr. Benjamin Rush, Professor of the Institutes and of Clinical Medicine in the University of Pennsylvania, took bold grounds against yellow fever being caused by contagion. He says: "I expected the fevers of the summer and autumn would be of a violent and malignant nature. I was the more disposed to entertain this opinion from observing the stagnating filth of the gutters of our city; for the citizens of Philadelphia, having an interest in rejecting the proofs of the generation of the epidemic of 1793 in their city, had neglected to introduce the regulations that were necessary to prevent the production of a similar fever from domestic putrefaction."

"From none of them had I observed the fever to be propagated by contagion, and therefore I took no steps to alarm my fellow-citizens with the unwelcome news of its being in town."

"On the 25th of the month, 1794, two members of a committee appointed by the Government of the State for taking care of the health of the city, called upon me to know whether the yellow fever was in town. I told them it was, and mentioned some of the cases that had come under my notice; but informed them at the same

time that I had seen no case where it had been contagious."

"As I considered the filth of the gutters and the stagnating water in the neighborhood of the city to be the remote causes of this fever, I advised the committee to have them both removed, and thereby to prevent the spreading of the disease."

Dr. John Brown, in his writings on the subject of yellow fever in America, says: "It appeared six different times, and all about the same time in the year, about the first to the middle of August, and declined or ceased about the middle of October."

"In the years 1732, 1739, 1745 and 1748 in Charleston; in 1791 in New York, and in 1793 in Philadelphia, and in every locality and season it has been proved beyond a doubt that the disease was caused by the influence of the weather, or the vicissitudes or surroundings of that particular locality, and not from contagion. Let a person in the height of a pestilential disease be removed from the atmosphere which occasioned it to one more pure, he will communicate the infection to no one." He then quotes Dr. Rush in speaking of yellow fever in Philadelphia, when Rush says: "This fever did not spread in the country, even carried there by persons who were infected and afterwards died with it." This position taken by Drs. Rush, Brown and others of olden date was fully sustained during the last scourge of yellow fever in the southern cities. Refugees from the south were received in many cities and towns of the north, middle and western States, but were not allowed to bring with them any of their household goods or clothing.

The following preamble and resolutions were unanimously passed by the Mississippi Valley Medical Association, held in St. Louis in September, 1888:

"WHEREAS, The existing deplorable condition of a considerable portion of our southern territory, induced by the spread of epidemic disease and the alarm thereby caused; believing it to be the duty of this Association, in view of the pressing exigency, to take every step possible to allay panic and reassure alarmed communities and states; therefore, be it

Resolved, That a committee of not less than five persons be appointed by the president to consider the present situation and report to this Association at a subsequent session what action in their judgment should be taken to secure the desired end."

The committee on yellow fever presented the following report, which was unanimously agreed to:

Resolved, That it is the sense of this meeting that yellow fever is not contagious in the ordinary sense of the term; that it cannot be communicated from the sick to the well.

"That the mildness of the present yellow fever invasion and lateness of the season, warrant us in strongly deprecating the fear now existing in many southern communities, the present rate of mortality being not greater than that which ordinarily obtains in typhoid fever."

"That the self imposed quarantine regulations now in force in the States north of the infected districts are not

only absurd, but inhuman and unworthy of the age in which we live.

"That quarantine regulations, to be effective, should apply to baggage, clothing and effects, rather than to the person of the individual.

"That when such effects come from infected districts they should be destroyed by fire, and the owner reimbursed from public funds.

"That cities and towns to the north of such districts and upon lines of travel may safely provide hospitals for the reception and care of the sick." George Homan, M. D., Missouri; J. A. Larrabee, M. D., Kentucky; David S. Booth, M. D., Illinois; J. D. Griffith, M. D., Missouri; G. A. Collamer, M. D., Ohio; George N. Kreider, M. D., Illinois; A. P. Waterfield, M. D., Tennessee, and A. W. Williams, M. D., Hot Springs, Arkansas, Committee."

Being a member of that Association, I was present and greatly interested in the candid, fearless and able discussion that followed those resolutions. Many of the members were well posted in the disease, having had practical experience; while the secretary of the Illinois State Board of Health was present, being on his way home from a full investigation of yellow fever in the south, and delivered a very able and clear address before the Association on the subject.

On my way home from St. Louis, September 28, I visited Louisville, which city had opened hospitals for the reception of yellow fever patients brought from the infected places south. Those sick were placed in the hospital without any household goods, or clothing worn by them at home, and no person, nurse or physician attending the cases had the disease in any of its forms. Of course I visited them while there to post myself in the disease.

We have a great craze on other diseases which are now pronounced contagious. Phthisis pulmonalis, pneumonia, and many other diseases of like character are pronounced contagious, yet all practitioners of experience must agree that they are not propagated by contagion.

For the last thirty years many of our most earnest medical gentlemen insist that diphtheria is a contagious disease, and in place of educating our citizens to look well to cleanliness of the surroundings and purity of the air breathed, the water for drinking, cooking, etc., as well as to the purity and healthy condition of food used, they are taught to shut themselves up in their damp, musty houses and not allowed either good air or sunlight, and no one allowed to go into their dwellings, to give aid and assistance to the sick and their families, and also public funerals prohibited. Why all this? Why not, on being called to a house where diphtheria exists, at the very first investigate and examine the house from garret to cellar and all the surroundings of the house, supply of water, outhouses, drainage, etc.? We all know that this disease is a filth disease, caused by bad air, water and food, one or all, and that it is a constitutional or blood (poison) disease. I will refer to the condition of one small town of about 200 inhabitants.

In May, 1876, I was called to B—, by Dr. H., to consult and advise with him in his course of treatment of diphtheria. On my arrival I found that eighteen had died and twenty-two were sick. The treatment in use was mercury internally and the local use of tincture of iron to the membrane. This treatment was at once discontinued and my usual constitutional treatment adopted—chlorate of potassa, chloride of sodium, bicarb. of soda, quinine, iron and stimuli as the case indicated; also free bathing, etc.

The great mystery to be solved by the doctor and citizens was where the contagion came from, as there was no other case of diphtheria in the surrounding country, and no one had been away or any stranger known to have visited the place during the spring. After a preliminary inspection of the location, to settle all questions, I called them to a mill-race leading from a dam, situated above the town, to a saw and flouring mill at the river below. This dam was used to hold water for the mills, and logs were floated down the stream and held in the dam to be passed out in the race as required. The mills required repairs and the water had been shut off from the race, which was close by and parallel with Main street, in the bed of which were found rotten wood, dead animals, in fact all kinds of filth and vegetable matter in an advanced stage of decomposition. The air was filled with noxious odors, which were almost intolerable. Their attention being called to this condition of things, all question as to the cause of contagion was considered settled. I at once directed that this mass of filth be raked up and burned, the bed of the race strewn with fresh lime, fences, outbuildings and cellars whitewashed, and quicklime placed in the rooms of each house and allowed to air slack. The result: One of the twenty-two patients then sick died, one other case developed about this time, who, with all the others, recovered. Of a total of forty one cases nineteen died, and twenty-two recovered.

We can truly say the same of cerebro-spinal meningitis. Are we progressing in thus ignoring science and every principle of hygiene?

Many other diseases of this day are treated in the same way, by depletion and local means, as if they were merely a local disease, and calomel, mercury and opiates used when tonics, stimuli and constitutional means should be employed during the entire course. Let us think, use reason and act at once.

Among the medicines resorted to in many cases by the old practitioners was the free and excessive use of opium. It was freely given in nearly all cases, especially inflammatory diseases, and was recommended strongly in the treatment of yellow and other fevers. In the old Brunonian system it was carried to a fearful extent. Dr. Parr says the effect of opium on the living body

has been represented in very opposite contradictory terms. It has been keenly disputed whether it was a stimulant or a sedative. If by stimulant is meant a medicine which, by its action on the stomach, will increase the heat of the body and quickness of the pulse, it by no means deserves the title. If given to a healthy person the pulse and heat are both lowered, and if the dose is increased nausea, faintness and headache follow, when the influence of the medicine is at an end. This brings it within the class of narcotics. When the change in the ideas of the circulating fluids was abandoned it was doubted whether it acted upon the stomach or heart, and the second Monroe has published some experiences which seem to say that its chief effect is on the latter (heart). This, however, only proved that when opium is injected into the sanguiferous system it produces no effect at all until it reaches the heart.

If fevers consist in debility and irregular action, and opium is a sedative, producing also irregular action, it will appear that no medicine is so unsuitable to the disease. This was the opinion of Dr. Parr.

All authorities agree that opium acts as a sedative or narcotic. It has been given to allay pain, produce stupor and sleep, but the drug was used promiscuously by the old practitioners of one hundred years or more ago, and now, more especially, its use is being revived to a fearful extent. It is employed by practitioners of respectability, I may say in nearly all the cases they meet with. It is used to save trouble of investigating and examining into the cause, remote or exciting, of the disease they may be called to treat. Patients have been kept under the influence of hypodermic injections of morphia, not only for days but weeks, without investigating the cause of sickness. When visiting a patient they should never leave the bedside until satisfied what indications they have to meet, and what will meet the indications and thus remove the cause, and not stupefy or paralyze the actions of the heart and all organs of the body, and deprive them of their ability to perform what nature has designed them to perform. It is time the profession frown upon such evasions of duty. Daily I am called to see patients that have been under the treatment of either opium, morphia or hydrate of chloral by the mouth, of morphia or cocaine by hypodermic injections, without any regard to the cause of the disease or the effects that these drugs are producing. Some years ago I was called to see a patient who had been treated about three months for what they called rheumatism of the knee joint, by a constant course of hypodermic injections of morphia at the knee. I investigated the leg above the knee and found the patient suffering from carious bone: I at once cut down to the femur on the inside of the leg and obtained a free discharge of thick offensive pus. By scraping

the bone thoroughly, carefully and freely, using washes and disinfectants, it soon healed from the bottom, and up to this day he has never had any pain or further trouble with the knee joint. I knew a case about three years ago of a young man who had cut his leg while working in the woods. This cut was filled with morphia before dressing it, which of course produced stupor, and he remained unconscious, constantly rolling his head and moaning until he died.

The effects and results of the abuse of opium could be multiplied from my own experience to pages, but will refer you to what Pomet says: "Its effects are always narcotic, whether used externally or given internally; given in clysters it operates quicker than by the mouth; applied to the eyes and ears, it has caused blindness and deafness, and a plaster of it on the head has caused death. It ought not to be given to plethoric persons without first bleeding them, nor at all to women at time of the menses, etc., nor even upon a full stomach, for it prevents digestion." (Pomet's History of Drugs, Fourth Ed., page 216, A.D. 1748).

We have quoted what Parr says on the use of opium, also, and in this it will be seen we have made but little progress, but are falling back into a worse condition and habit of practice than has existed in all the history of medicine. Can it be reformed? Can we progress from this time onward?

At this time the country is crowded with those practicing medicine under some system they claim to be the only one founded on reason and science. The Thompsonian practice was advocated by Thompson, of New England. He claimed the human body is composed of four elements, earth, air, fire and water, and that metals and minerals are in the earth, and these materials being taken from the earth, have a tendency to carry all back into the earth who use them; and as the tendency of all vegetables is to spring up from the earth, and therefore to keep mankind from the grave, all medicine must be vegetable. We all remember how they scattered their hot drops, No. six, and vegetable composition, over the country.

Homeopathy is a system which maintains that disease in the human body must be cured by producing other disordered actions of like kind (*similia similibus*), and this is to be accomplished by infinitesimal doses, and really nothing but sugar of milk at that. The whole practice and system is visionary.

Hydropathy is another system, which is founded upon the treatment of all diseases with water, packing in wet sheets, etc. Yet this also has its followers and advocates.

Vitapathy, Vita—Life vs. Pathy—Disease. Of later years we have this system, which puts on more nonsense than all the others. Its advocates say they have the only true system of health and

life, and the American Health College in Cincinnati gives the highest diploma of any college in the United States.

There are many new things in Vitapathy. For instance, "our electro-magnetic warm air bath surpasses all hot springs, magnetic springs, electro-thermal, Turkish, or any kind of vapor, heat or electric baths, as it combines all those and much more, uniting oxygen, heat, light, electricity and vital magnetism all in one luxurious, cleansing, purifying, invigorating and vitalizing process, developing youth, invigorating age, increasing beauty and prolonging life. This bath is used mostly for colds, rheumatism, neuralgia, fever and ague, malarial and bilious diseases, nervous and chronic diseases generally. Healing by the laying on of hands, together with the new discoveries in Vitapathy, makes a grand, successful, powerful treatment. This is what we practice and what we preach, and with a full knowledge and faith in this doctrine can annihilate disease, banish wrong, open wide the gates of life, break down the walls of hell, kill the devil, perfect our manhood and make this world a paradise."

The above is a slip cut from one of the notices announcing their system, etc.

Eclectic practice has had its day under that name. They claimed to elect the best means used to treat disease from all systems up to their day. Eclectics were, and are now, nothing more or less than a combination of the old botanic or root doctors and Thompsonians, and under this name, eclectics, their school or so-called college for this country, was at Cincinnati. Agents often canvassed the country with diplomas filled, except the name of the person they graduated, and filled them out for those that would pay twenty-five dollars.

Botanic System. There were also persons who claimed to be doctors and treat diseases with roots, herbs and barks.

When I came to Elk county in 1846, four were in active practice. They usually took with them a school basket filled with "catnip" (*nepeta cataria*), "mullen leaves" (*folia melezomum*), "smart weed" (*polygnum hydropiper punctatum*), "boneset leaves" (*folia eupatorium perfoliatum*), "mandrake root" (*rad podophyllum peltatum*), "butternut bark" (*cortex juglans cinerea*), "pennyroyal" (*mentha pulegium*), "tanasia or tansy" (*tanacetum*), "dandelion root" (*leontodon taxacum rad*), "skunk cabbage root" (*rad dracontium foetidum*), "elecampane root" (*rad inula helenium*), "cranesbill root" (*rad geranium maculatum*), "pipsisiwa leaves" (*folia chimaphila umbellata*), and a host of other weeds and roots.

Christian Science, etc. Every age has its delusions and their victims, including our own, notwithstanding the growth of knowledge and the rapid and boasted advancement we are making

in our system of education. Some of these delusions, frauds and humbugs are now perpetrated under the shelter of the words, "Christian Science." This system of concentrated nonsense has been invading our country and has its followers. There are different schools, and they do not agree in all particulars, but unite in one thing, there is no such thing as matter; all is "mind." They contend all disease is an error; that we are not sick, but think we are sick; that we do not die, but think we die. Strictly speaking, there is no such thing as "disease." What men imagine to be disease is an error of their own minds. Then comes the Faith Cure; a class of pretenders who have many followers and believers, who forsake their physicians at home, allow themselves to be humbugged for a time by what are called "Faith Cure Doctors." In every case I have known, patients suffering from disease, return to their homes for treatment.

We also have Pasteur, Brown-Séquard, Koch, and others, with their "isms and cisms."

By referring to the early writers, there was a class of physicians then that we of this day call specialists. Each physician applied himself to one disease and not more. This system in days of the limited facilities for medical education, especially in anatomy, physiology, materia medica, therapeutics, chemistry, etc., was very proper, but at this time every student should be thoroughly educated in all the diseases of the body, all the surroundings of these diseases, and be ready to meet each indication.

In the country we see the evil of the present system of specialism to a greater extent than is seen in cities. Daily we meet with cases sent to cities for special treatment, such as affections of the eyes or the ears, headache, rheumatism, tumors, ulcers, lungs, rectum, bowels, stomach or liver, and female diseases, and returned after a long stay with no improvement, and often in a much worse condition than when they left home. Why? The treatment was for a symptom and not the disease. They extensively advertise their specialty. Some call themselves cancer doctors and draw many to them for that disease, and finding a tumor on some part of the body, pronounce it cancer and use the knife to remove it, when if they would stop and think a moment and call to mind the cause of these tumors and ulcers, would never use the knife until the system was prepared by constitutional treatment. In a malignant tumor or ulcer, why remove the symptom and leave the cause to reproduce it? They do, however, and take their money. We all know if they are cancers they will in every case return, in due time, unless treated by some regular physician constitutionally, thus purifying the blood generally by getting the malignant disposition of the body eradicated. Another class of these doctors use caustics and plasters,

as they say, to eat them out, with the same or worse results. We should remember what Hippocrates says on cancer: "It is better not to cure hidden cancers, for they who are cured quickly perish; whilst they who are not cured live longer." Then why tamper with human life, under the name of "Specialist?"

Thus it will be seen that the medical profession at this day have the same trouble with quacks and quackery as is referred to in the writings of Hippocrates, Herodotus and others, when it was said: "Even at this day there were designing men who were physicians only in name, and who gave themselves up to disreputable practices; against whom the regularly initiated had no redress." Are we not placed in somewhat the same condition, and with no other hope or redress than to stand together as a band of brothers, in our regular Medical Society, County, State, District, American and International Medical Congress, and advocate the elevation of the profession, not by legislation of States or Congress of the United States, but by requiring a superior education of all applicants for "illumination, inspection and coronation," also honesty of purpose and devotion to their duties, etc? Thus standing together as one educated body, let us frown upon every effort to bring down our high standing to the level of those before referred to. If we expect protection by legislation, remember laws passed by the legislature or Congress of one year may be undone in another, and we must expect to be ever in doubt as to our standing.

How are we to elevate the profession of medicine and surgery? Is it to be done by passing laws reflecting upon the honesty and ability of our medical colleges, and declaring the diplomas granted by them worthless and to be treated as so much waste paper?

The several States have chartered medical colleges in their respective States, and granted them full power to receive students and graduate them, or confer the degree of Doctor of Medicine, which diploma should be good all over the world. The requirements of these colleges for receiving students and conferring the degree of Doctor of Medicine, etc., should be the same in every State of the Union, and should be marked out by the American Medical Association, and all colleges required to fully carry out the rules and requirements, and see them faithfully enforced as follows: The American Medical Association directions to be strictly observed by the medical colleges of the several States. To regulate the study of medicine and surgery, and defining the duties of students, preceptors and the medical colleges. Be it resolved, by the American Medical Association at its annual meeting held at—on—day of—month, A. D.—, and it is hereby declared by the authority of the same,

that from and after the first day of—month, the medical colleges of the United States of America shall require all students of medicine and surgery to present to the Dean of the college he or she proposes to attend, a sworn statement that he or she commenced the study of medicine and surgery in the office of—, M.D., practicing physician and surgeon, on the—day of—A. D.—, and studied two years in his office and under his directions and instructions. Also the student to present an affidavit of his preceptor: I, —M.D., practicing physician and surgeon of the—, County of—State of—, having made a full and thorough examination of—, of—, of—, and State of—, whose name is written in his own proper handwriting on the margin of this certificate, do hereby certify that he was found well qualified in respect to moral character, learning and ability to be admitted as a student of medicine and surgery, and on—day of—, A. D.—, he was duly received in my office as a student of medicine and surgery, and continued under my instruction and inspection for the term of two years to the—day of—A. D.—, and during that time has proved himself in every way worthy.

Signed, —M.D.,

Practicing Physician and Surgeon.

Sworn and subscribed before me this—day —A. D.—.

In the country it is well known that a young man working in the woods or acting as clerk, at the time of the opening of a course in a medical college, leaves for college and returns at its close, begins the work he was engaged in before, and finally returns an M.D. He is recorded as a student of Dr.—, whom, as is frequently the case, the doctor never knew.

Students should be required to read the medical authorities under the inspection and direction of their preceptors, and thus be able to understand and know what our professors are talking about. Shall we allow our medical colleges to be treated as frauds and humbugs? All of which is respectfully submitted.

DIPHTHERIA.—H. Wolf (*Fortsch. d. Med.*, 1890, 8, 954) has used a combination of menthol with sugar in the proportion of 1 or 2 to 20 in the treatment of diphtheria. This powder he rubs upon the parts affected by the disease. The deposit often sticks to the brush and is removed by it. The brush is then again carried into the throat and the menthol-sugar thoroughly rubbed into the part. This procedure is carried out two or three times daily. Even by the second or third day the dirty-gray appearance disappears, and a clean excavated ulcer remains which quickly heals under the continuance of the treatment. To control the fever he employs antipyretics.

ANTISEPTICS.

Read in the Section of Practice of Medicine, and Physiological Therapeutics, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C. May, 1891.

BY HIRAM CORSON, M.D.,
OF PLYMOUTH MEETING, PA.

There has been a decided tendency for the past few years on the part of persons affected by the antiseptic and germ theories, to make it imperative on those who practice midwifery, to obey the rigid antiseptic rules laid down by teachers. I saw somewhere that in a discussion on the necessity for antiseptic measures during parturition, and their continuance during the lying-in period, a prominent physician said "that if he should be called on to testify, in a prosecution for malpractice where death had occurred during confinement and antiseptic precautions had not been used, he would certainly testify that it was criminal malpractice." This was an alarming threat, as it placed practitioners of midwifery in constant peril, and it impelled me to speak to our County Medical Society about it, and to urge them to make some preparation for such an emergency. The Society then appointed me to procure from practitioners of long experience—men who had attended hundreds, and even thousands of women in labor—statistics in relation to the fatality caused by peritonitis, during their many years of attendance on puerperal women. While a student of medicine in 1827 I had my first case of labor. Then there was no dread of puerperal fever being caused by germs, introduced into the uterus or vagina by the hand of the accoucheur, but the few cases which did occur were attributed to the powerful, long-continued uterine contractions, or to injury by the forceps, with laceration and subsequent inflammation of the parts, and to extension to the peritoneum. What obstetrician has not known how sore and tender, on pressure, the womb oftentimes was, when pressed upon soon after childbirth—even before Credé began his unnecessary and heartless wrenching and punching of it—and yet rarely did puerperal fever occur. So with this view of things I started in this specialty and kept at it for sixty years, attending more than three thousand women, ever amazed by the fact presented to me of the rare instances of mortality attendant on gestation and childbirth; the latter process and after-treatment of the mother being often attended by conditions which would now be considered extremely perilous to life, in almost every instance, by those who are pressing on us the use of antiseptics, to secure safety to puerperal patients. In those days our education in midwifery was little more than the details needed to conduct an ordinary labor. Oh! how poorly I was fitted to aid the patient in her apparently perilous work; and after the labor was over, how worse than useless, even dangerous were some of the well-meant measures of the

nurse. As soon as the child was born, a bowl of "tiff"—gin and water, or whisky and water sweetened—was given to the patient—nor was the doctor forgotten—and then for many days, as drink, hot teas, balm, pennyroyal and others, but not a drop of cold water. Such was the custom, but never mine. Forbidden as it was, I insisted on cold water as drink. I had attended a good many cases and had often, on my after visits, been met, on entering the room, by an odor recognized as that of putrid blood, and so offensive that it was unpleasant to remain there. I spoke of it to the nurses, but they said it was always so, and as I was a mere boy, when compared with the venerable matrons who, in those days, ministered to the lying-in women, who were so neat and clean in their own persons, I concluded that the "cloth" had perhaps remained there too long, and that its removal would do away with the fetor; so gave directions to have a fresh one applied, and went away. So things went on in most of the cases for a year or two. As a general thing the fetor was very evident for a week or more, and finally was so bad in one case, that I determined to see what condition the patient was in; when lo! I found that she had not had a single washing of the genitals and contiguous parts, or a removal of soiled clothes since the end of the labor, though a whole week had elapsed. On expressing my surprise and disgust that the nurse had left her in that condition, and without a regular cleansing every day, I was told that it was not the custom to do so, through fear that the washing and change of clothes would cause her to "take cold." I had succeeded an aged practitioner in that region, and so I suppose the practice had gone on during many years with the nurses for the majority of lying in women. If these women thus treated, with no antiseptic measures before labor, none during it, nor afterward for the proverbial "nine days" which were to complete the lying-in period, passed safely through this ordeal, and repeated it again and again, not one in many hundreds suffering from puerperal fever, is it reasonable that other precautions are more needed than those of cleanliness obtainable without the use of antiseptics, which are now so much used, and which, from their poisonous nature, have in some cases caused the death of the patient?

From the first days of my practice up to the present time, in threatened abortions or miscarriages, when there was slight hemorrhage going on, a like fetor has been noticed in nearly every case (when the clothes were raised in order to examine the patient), day after day until the ovum was cast off; the vagina being filled with clot and putrid blood. The justly celebrated Professors, Dr. Chalkly James and Dr. Wm. P. Deucer, teachers of midwifery in the University of Pennsylvania sixty-two years ago, directed us in those

cases to tampon the vagina, so that the woman would be safe during the absence of the physician, but every day to remove it, and have a fresh one to take its place, or the same one washed and soaked in vinegar and then replaced. Thus I have sometimes had cases go on from day to day for nearly or quite a week, before the uterus was sufficiently opened—we did not force it open then—to remove the ovum; and seldom have I known anything more offensive than the sponges and putrid blood which were in the vagina, when I attempted their removal, and yet in not a single case in all my sixty years of practice did any of these patients suffer from puerperal fever, or peritonitis, or any other fatal affection of the pelvic organs. In such cases the woman was often examined to ascertain whether or not the abortion was likely to occur, or whether the ovum could be removed, and it was sometimes—often, indeed—necessary to remove the ovum, or the secundines through which the fetus had slipped, leaving them in the womb, but the patient, though sometimes pale and weak, would soon rally and be herself again.

Why then, I ask, if by such practice—whether it was right or whether it was wrong—no harm came to the patient, so far as life was concerned, need we now, when we have good nurses and great cleanliness enforced, use antiseptic precautions and measures or be in danger of criminal prosecutions based on the testimony of obstetrical experts, who see infectious germs under every finger-nail, yet who have never attended half a dozen cases of labor and do not know that we object to the use of antiseptics because several women have lost their lives by the use of them as directed by the germistes, though thousands of women in our State suffered abortions every year and got well without a set-back. Two days ago, a physician who has practiced for twenty years and has had a large practice, five cases last week, wrote to me: "As for germs, if they are as numerous and as rampant as writers and teachers would have us believe, then almost every puerperal woman in the country ought to die of peritonitis. The scrubbing and squirrings may be all well for hospitals, but in communities of decent people, they seem to me useless and worse than useless." Very recently a writer has given us his opinion, that the physician should take charge of every woman, whom he expects to attend during labor, at least three months before the time of expected labor, and direct her diet, and baths, and everything that aids in keeping the infectious germs at a distance. And about two years ago another physician gave a caution to those of us who might find it necessary to use a rectal injection, to be careful not to let the germs in by that back-door. Why these great fears? Are not women now as they were fifty or sixty years ago and have always been since that time? And did not they

then pass through the labor process under less favorable conditions than now, and yet without peritonitis in more than one of a thousand cases? and even that *one* perhaps the result of violence and not caused by germs. And yet were not the germs as numerous then as now? Ah! here the germistes possibly have me; for half a century ago farmers grew potatoes without difficulty; they put the cuttings in the ground and they grew amair. Nothing disturbed them; but now what a change! They are planted, send up their stalks and leaves and give promise of a crop; when lo! in a single night, the potato-bug. The beautiful black and gilded germs fasten on the growing plant, and if the Paris-green, the germicide, be not at hand, the plant dies from the destruction of its lungs. So, it is plain that one generation may have no secret, deadly enemy to bring death to happy homes, and yet the next have one. But is it so here? Certainly not. The man who practices alongside of the frightened antiseptic doctor sees not, fears not any venomous germs, and his patients rise from their beds happy in their love of offspring.

Counting but ten miscarriages to every hundred labors, I must have had more than three hundred in my practice, very many of them—indeed, nearly every one of them, being in the condition described above—the vagina, and sometimes the uterus, containing putrid blood for many days, and yet not in a single case did peritonitis occur. The same conditions have been presented to thousands of other physicians in cities as well as in the country.

As we are now directed by teachers to use the rigid antiseptic measures of the present day, even when attending the healthiest woman, and though no infectious disease prevails in the neighborhood—and threatened with prosecution if we do not—it is pertinent to inquire what has been the result in the last fifty years in the practice of physicians who took no precautions against carrying infectious diseases from patients whom they were attending to those women to whom they were called when in labor.

As I was not more successful in my obstetrical practice than other doctors, an account of my experience in this branch of our business will fairly represent the practice and results of the profession for the whole sixty years during which I was in active practice, 1828 to 1888. When attending patients ill with measles, scarlet fever, small-pox or erysipelas, I visited my other sick people, including puerperal ones, the same as though I were not attending an infectious disease. There were but few cases of small-pox came under my care—not more than 15 or 20 perhaps, in all my long practice, and only two proved fatal. One, who recovered, I not only visited as a physician, but through the refusal of the "Poor Directors" to receive him at the almshouse, and the fear of

the family in whose house he was, I felt compelled to visit him twice daily and attend to all his wants during all his illness. I visited families without taking any precautions against conveying the infection to puerperal or other patients.

Scarlet fever prevailed greatly at times during my first thirty years of practice. In a severe epidemic of it, one winter, I had more than eighty cases. Every day of that winter I was in attendance on them, and during that time had many obstetrical cases, and in my sixty years of practice I, of course, had many hundreds of cases, and yet I did not carry any scarlet fever germs to infect a single lying-in woman, though I sometimes went directly from attendance on these cases to the woman in labor. Even more than that; when my children, nine in number, had the disease at different times, two or more at a time, and I nursed them and slept in the room with them, I went, if called to a case of labor, straight to the patient without taking any precautions against conveying the disease to the woman. Some persons, even at that time, inclined to the belief that the infection of measles, scarlet fever, small-pox, and notably erysipelas, might be carried from the infected houses in the clothes—not under the finger nails—and therefore changed their clothes if attending small-pox patients. At that time the dirt under the nails was not known to be the nidus of germs, and washing and scrubbing the hands for the special purpose of dislodging them was an unheard of process.

I believe as fully in the infectious nature of measles and scarlet fever as I do in the contagiousness of small-pox, and yet in my visits to families where the children had never had these diseases, I never carried it to them from other infected patients. If there be danger or a possibility of the infection being thus conveyed by a physician, I think my exemption from being a carrier of it must have been due to the short time spent in the sick room, or to the sometimes long ride in the open air to the next place visited. Even more dreaded than the three diseases is erysipelas as a cause of puerperal fever. As with the others, I took no precautions. If attending a case of erysipelas, if a call were made on me to go to an obstetric case I went at once without using other precautions than with the other three diseases.

Here allow me to report a single case: January 17, 1860, I was called to Mrs. Rey, a young wife within a few days of her expected labor. I found her with enormously swelled oedematous labia, which kept her limbs widely separated. There was an erysipelatous redness covering them. Measures were used to relieve her, though with little change in the size of the swelling, while the erysipelatous redness increased in intensity and extended to the contiguous parts of the thighs.

On the 20th I was called in haste, as she believed labor was approaching, but as the pains were trifling I left her, after waiting a couple of hours, and from that time was frequently with her until the 23rd, when the child was born alive. The labia were then greatly discolored and before her death, on the 29th, sloughed badly. Peritonitis was evident soon after her labor terminated, and was the cause of her death.

Now, between January 17, the day of my first visit, and the 20th, when I was with her two hours, I attended two other women—Mrs. Henderson on the 17th and Mrs. W. on the 19th. And on leaving Mrs. Rey on the 20th, at eleven o'clock P.M., was in attendance on Mrs. Righter at one A.M. on the 21st, and assisted in her parturition. From this statement it appears, not only that I was visiting and in attendance on the first three during their labors, while in daily attendance on the erysipelatous case, and that in two hours after I had examined Mrs. Rey, or had attempted to do it, but failed because the labia were so swelled that I could not succeed in reaching the os uteri with my finger, I was in attendance on Mrs. Righter, and continued with her for some hours, occasionally examining to mark the progress of the case. And after this, when Mrs. Rey's labor terminated, I continued to visit Mrs. Righter and the others as often as was my usual custom, and they all did well. I know full well that all this is not conclusive proof that the poison of infectious diseases cannot be carried from one person to another in the usual way of visiting patients, and in labor of handling them, but it is strongly against such a probability. I have merely stated facts, carefully recorded during many years of practice, for the consideration of readers. When, in 1863, I published two thousand three hundred and thirty-seven cases afterwards swelled to three thousand and thirty-six I discovered that few, if any, physicians in our populous country had careful records of their cases, but that they had to depend on their memory if they wished to speak of them in after years. What I have written here is from a careful record made thirty years ago, when I had no expectation that I should ever again have need to refer to these facts. And now when I add that in all this long practice of sixty years, and in profound ignorance of poisonous germs being carried in my clothes, or in the dirt—when there was any—under my finger nails, that though in attendance on 3,036 women in labor, I never once carried an infectious disease to them, I feel that I might rest my case here. But I prefer to add the experience of some experienced physicians in relation to the occurrence of puerperal peritonitis in lying-in women. Professor Traill Green, M.D., of Easton, Pa., known to the profession everywhere in our country, has practiced fifty years, and on enquiring of him in relation to the now

dreaded puerperal fever he replied: "I have been so happy as to have no case of puerperal fever, and I think it has been very rare in the practice of fellow practitioners." Would it be possible, think you, to convince this experienced man who has watched by the bedside of suffering women during half a century, that it is now necessary for him to begin, three months before a patient's expected labor, to visit and prescribe for her, regulate her diet, direct the times for taking exercise, advise her when to bathe, etc., healthy so she be, and when the labor has begun, to scrub his always clean hands, dip them in a solution of corrosive sublimate, bathe the genitals of his patient with it, throw some of it into the vagina, and even into the uterus, keep it by his side, so that he may dip his hands in it every time before "touching" his patient; and then when the child has come and the placenta been removed, to throw a solution of corrosive sublimate, by means of a powerful syringe, into the cavity of the womb "to wash out the blood clot?" I repeat, do you think he would believe such proceedings necessary?—even if we had never heard of the many deaths which have occurred from antiseptics having been used to wash out the uterus after delivery?

But let me pass to other testimony. Another friend of mine, a graduate of the University of Pennsylvania, 35 years ago, a man of undoubted truth, writes: "What nonsense is all this stuff about perineal pads and douching the vagina before and after labor, and antiseptics in obstetric practice? However useful and necessary a certain amount of it may possibly be in lying-in establishments, it seems useless here. I have never had a fatal case of puerperal disease, and have seen but three or four in consultations."

Dr. Wilson, of this county, and a member of the County Society, writes: I have been in continuous practice for twenty years and have always had a large obstetric practice, my cases numbering between one thousand and fifteen hundred, and *have never lost a woman* (italics mine). I have never, as a rule paid much attention to antiseptics. In fact I have always looked upon labor as a physiological process, and the less it was interfered with the better the results.

Dr. J. B. Carroll, of our society, writes: "In fourteen years' practice there has only been one case of puerperal fever."

Dr. J. B. Walter, of Bucks County, says: "In 22 years' experience I have had considerable obstetrical business—five cases last week—and only two cases of peritonitis. One of them arose from a lacerated cervix; was very ill, but recovered. The other was a metro-peritonitis, resulting primarily from over-smartness, and secondly from unjustifiable battering and bruising of the uterine tissues, by a rather eminent man, who needlessly, after two hours successfully turned, and

with my aid delivered a dead body, to be followed in a few days to the land of shades by the mother. In this case all needful antiseptic precautions were taken."

Dr. D. Colvin, of Clyde, N. Y., replies as follows: "Though compelled to relinquish active practice for a time, yet I can report attendance on 1,279 cases, exclusive of consultations. I have never lost but one woman, and she died a few minutes after the placenta was removed. In not one single case have I ever used antiseptic treatment, and have never had a case of puerperal peritonitis, but have seen two or three in the practice of others."

"When I think of the hundreds of women whom I have delivered in log-houses and board shanties, long before the antiseptic treatment was thought of, and have seen those women up in a few days, and caring for their children, with their health unimpaired, not one of them dying, it teaches me that the caution given to us by our old professor of midwifery: 'Beware of Meddlesome Midwifery,' was timely and proper."

"My father, too, was in practice from 1817 to 1876, and I know of only one case of puerperal peritonitis in his practice."

Thus could I go on with just as strong testimony from a thousand country physicians, but it is not necessary, for I would be told of the wonderful achievements of our present surgeons, due mainly, as the germes believe, to the use of antiseptics in their operations. Their success has been marvelous; but was it due to antiseptics? Are there not many successful surgeons and gynecologists who do use them? What stronger testimony can be given for the success of surgeons who use antiseptics, than have been given by our own Goodell, Sutton, and Joseph Price, and Lawson Tait of England, of their unrivaled success in surgical and gynecological operations, by cleanliness, without the use of antiseptics in the surgical treatment of puerperal and non-*puerperal* women?

As their testimony is not at hand I quote from Dr. George Dean, of Spartansburgh, S. C., who spent some days on a visit to the Gynecean Hospital, in Philadelphia, under the supervision of Dr. Joseph Price and Dr. Charles Penrose. "This hospital is a model in its way. It is new and small and lacks many conveniences of some other hospitals, but the lack of them is more than counterbalanced by the skill and enthusiasm of its chiefs, and their determination to achieve a success for it second to none in the world. It already stands at the head of such institutions in the United States. I witnessed many operations there—abdominal sections and plastic operations upon womb and perineum; success in every case followed. I have seen pustules as large as small intestines, adhesions so great that the bowel would tear before the adhesions would break,

and all anatomical relations obliterated in the pelvis, and yet these patients made an uninterrupted recovery." To this I may add that in the Gynecæan Hospital in a series of 80 consecutive cases there was not a single death—and that in one hundred sections, done in alleys and courts in the service of the Phil. Dispensary, but a single death occurred, and that was done by an assistant. In not a single case were chemicals used. There is a disposition in some—many—eminent physicians to discredit the statistics of those general practitioners in the country who report a light mortality in their hundreds of cases. They will, I feel assured, question the testimony of Dr. Traill Green and the others cited by me, and I desire to add a few more to the above, just as reliable. Dr. Kemper of Muncie, Ind., in *Medical and Surgical Reporter*, June 22, 1889, reports 900 cases of which only two women died, one of puerperal convulsions, the other of pneumonia. He also reports that Dr. J. T. Chenoweth had 1,600 labors with only one death; Dr. N. T. Chenoweth 708, 2 deaths; Dr. A. H. Farquar 500, 2 deaths; Thomas Botkin 525, 5 deaths; Dr. J. S. Blair, 419, 2 deaths; total, 3,752 with 12 deaths; less than one death in 300 attended—and no antiseptic precautions taken. He pertinently remarks, "I have the honor of a personal acquaintance with the physicians mentioned, and I trust them as implicitly as I do physicians in lying-in hospitals. I am not aware that a country practitioner is more prone to exaggeration than his city brothers, or that falsity was indigenous to rural localities."

Dr. William F. Mitchell in "*Reporter*" of Oct. 5, 1889, gives the following testimony. That he has been in practice 24 years, has had more than 700 cases; has never administered, or caused to be administered to any woman any antiseptic remedies before or after parturition, and has never lost but one woman, and she was confined prematurely and under all the circumstances could not have expected to live. I prefer generally to present the testimony of others rather than my own, but I may say here that my 3,036 cases are confirmatory of what has already been given by the practitioners alluded to. A detailed account of them may be found in *New York Medical Journal* for May 15, 22 and 29, 1886.

Tedious as I have already been, I must go further, as this is an important subject, and get some testimony from "abroad." In the American Medical Association JOURNAL of December 28, 1889, we have Dr. Bantock's views of Listerism. Allow me to briefly state some of his facts. He says, that in 1881 only Mr. Lawson Tait and himself dared perform operations without using the rigid listerian details; but in 1889, in England, it was a rare thing to see the spray used at all; and in the Samaritan Free Hospital it has been discarded by all his colleagues with one ex-

ception, and that this is due to the superior results obtained there, since he resorted to a more rational and simple method. Speaking of ovariectomy he records it as a fact, that from April 1883, to October 1888, 3½ years, he did not lose a case in the Samaritan Free Hospital in a series of 90 cases, while during this period the deaths under the listerian system exceeded 12 per cent., and his patients recovered with less pyrexia than did those under the carbolic acid treatment. For his hands, sponges and instruments, he uses no antiseptic—only plain water—regards water that is fit for household use, suitable for the purpose of any operation, and has no hesitancy, if too warm for his hands, to cool it with cold water fresh from the tap—as, for instance, when washing out the abdominal cavity. As a covering to the wound he uses simple absorbent gauze, innocent of any germicide, and such is his belief in its harmlessness, that were it not for other considerations he would leave all his wounds exposed to the air, as he has sometimes done in amputations of the breast. He attributes the bad results which so often occur from washing the peritoneum to the employment of antiseptic material in the water, which becomes absorbed, or in some way poisons the patient. We know full well, that some persons are peculiarly sensitive to the toxic action of corrosive sublimate and that, though in a majority of cases no harm may result, yet occasionally a case is met with in which this idiosyncrasy exists. This is the only rational way of accounting for the large number of deaths due to the use of carbolic acid, and more especially to corrosive sublimate.

He therefore protests against the use of so-called germicides in flushing the peritoneum; and cannot insist too strongly on confining the surgeon to plain water as at once perfectly innocuous and thoroughly efficient.

It appears from what I have written, that there is real danger to the woman from the use of antiseptics—more danger than there is in the practice of the physicians who do not use them. As confirmatory of this, let me refer to what has happened in the Nurses' Home and Lying-in Charity Hospital at the corner of Eleventh and Cherry streets, Philadelphia; a new building erected for the special purpose, I have been told, of illustrating the value of listerian treatment. Quite recently it had to be closed, because of a virulent epidemic which occurred within its walls. Surgery was done there as well as obstetrics, and reliance was placed upon chemical solutions, and everything done was under the supervision of careful and able surgeons and gynecologists. How does this compare with the Gynecæan hospital? Not at all. The success of the latter is in direct contrast with the failure of the former.

Need more be said? No. The testimony of Dr. Traill Green, known as he is everywhere as a

man of truth and honor, who has practiced midwifery for half a century, should convince every right-minded man, that there is no need that country physicians should take the precautions against germs, so strongly urged by the advocates of listerism. But Dr. Green is sustained by other good men whom I have named and thousands of others whom I could name. No, I need say no more, for if one were to rise from the dead and give like testimony, the antiseptic enthusiasts and laboratory practitioners would still discredit the testimony of the bed-side practitioner.

SOME CLINICAL EXPERIENCES WITH EUCALYPTOL.

Read by Title in the Section of Medicine and Physiology at the Forty-Sixth Annual Meeting of the American Medical Association, held at Washington, D. C., May 31, 1894.

BY L. N. BRAINERD, M.D.,

OF ALMA, MICH.

During the last ten years I have often prescribed eucalyptol in bronchial and pulmonary troubles. From this experience I have learned to put a high therapeutic value upon it in some respiratory affections, viz.: chronic bronchitis, persistent cough, chronic interstitial pneumonia, and to a less degree in tuberculosis.

The following list of cases taken from my later experience, furnishes a reasonable amount of proof of its utility:

Case 1.—Miss Bellard, aged 19. This lady called upon me in August, 1888. She complained of malaise, and some pain in the left lung. She had only a moderate cough and a limited expectoration. The temperature was 99°. Auscultation revealed a harsh and catchy respiration in the upper lobe of the left lung. A trifling dullness on percussion could be discovered in this region. I gave the girl eucalyptol, and had her visit my office every fortnight for half a year. She so far improved as to lead expectation of her recovery. Then, school beginning, she started to school. As cold weather came on, she was chilled one day in school, and developed a severe croupous pneumonia. For this she was treated by a physician in her town, but not recovering, I was called to see her. Resolution did not take place as it should, and I advised the mother that the girl would never recover from this sickness. After a few weeks she died. I believe that except for this intercurrent pneumonia, this girl would have continued to progress to a recovery from the phthisis. For a whole year she improved until she felt nearly as well and strong as ever. Then she sickened with pneumonia and died in two months.

Case 2.—Mrs. Thompson, aged 30. This lady called upon me in September, 1889. She was emaciated to a skeleton, had hectic fever, pulse about 90, cough with some expectoration and tenderness on percussion over both lungs. The respiration was catchy and frequent. She had almost a loathing for food and scarcely strength enough to come to my office. She had been ill for many months. I put her upon eucalyptol and cod-liver oil. She rapidly improved in all respects, and ceased to visit me after about two months. I had her under observation until all the objective symptoms, including the catchy respiration, ceased. I see her occasionally. She says my prescription has made a new creature of her. She is in her usual flesh and is doing her own work.

Case 3.—Mrs. Morton, aged 26, called upon me in September, 1889. She had a miscarriage in the spring. Upon rising from this sickness she took cold and developed a cough and soreness through the lung, from which she did not recover all summer. Neither did her menses reappear. She is from a consumptive family. These things alarmed her somewhat, and she applied to me for aid. Her respirations were harsh and catchy, and her cough was quite troublesome. I gave her a prescription containing eucalyptol, and have had her under observation ever since. Her respiratory murmur is all right and she has menstruated once or twice since, and now seems to have gone into her menopause at this early age. She is in perfect health.

Case 4.—Mr. Bradford, aged 30, called upon me in December, 1889. He complained of a pain in his chest and an inability to take deep inspirations with ease. Work involving the use of the pectoral muscles, as chopping, sawing, husking corn, etc., was painful. He was growing poor and emaciating. Physical examination of the chest revealed a little dullness on percussion over the upper parts of both lungs, and a harsh catchy respiration. I put this man upon eucalyptol, and watched the case for a year and more. The patient still complains at times of lameness in the thoracic parietes, but he now has less of the catchy respiration and none of the dullness on percussion.

Case 5.—Miss McLaren, aged 16. In February, 1890, I was called to see this girl. I found her in bed. She had a temperature of 102°, a pulse of 120, respiration 30, cough and expectoration. She had la grippe a few months before and had fallen into this state. Her respirations were harsh, tubular and catchy. I treated her symptomatically and put her upon cod-liver oil at once. After about a month she began to walk out, and then I gave her eucalyptol besides her cod-liver oil. She continued to improve for some months, when I permitted her to go from my care to Ohio, where she has since remained. When I first saw her, she was much emaciated, but now she weighs 150 pounds. The cough and expectoration have ceased, and she is now perfectly well. Several children in this family have already died of consumption, and I believe this girl had incipient phthisis. The only thing lacking in the evidence is the demonstrated presence of the tubercle bacilli. I made no search for them.

Case 6.—Mrs. Pulfrey, aged 34, visited me in February, 1890. She had been failing for some months. She complained of pain in her right lung. The percussion note was normal, but the respiratory murmur was catchy. I put her upon eucalyptol and Phillip's wheat phosphates. She soon began to revive in every way. The catchy respirations have ceased and the patient has nothing to remind her of her former condition except her feeble endurance.

Case 7.—Mr. Young, aged 27. In the latter part of 1889 this man was taken sick in Boston. He was treated for bronchitis, but finally had to go into a hospital. Here he heard the visiting physician, a college professor, say to a class of medical students: "We don't get hold of this case." After a few weeks' stay in the hospital he came to Michigan to accept the hospitalities of his brother. In February, 1890, I was called in to see him. I found him greatly emaciated, with a temperature of 101°, pulse about 90, respiration 28, and a violent cough, raising about a pint a day of frothy, bloody sputa, containing mucus, pus and blood. The sputa had a rank, gangrenous odor, and separated into two layers, one of fluid and one of foam. This was enough to make a diagnosis of gangrene of the lung. Physical exploration revealed a small area of flatness at the lower point of the right lung. The rest of the lung was a little super-resonant because of its doing compensatory work. On several occasions this patient had alarming hæmorrhages. I put him upon eucalyptol and cod-liver oil. He gradually improved under this treatment, and went to Canada to live upon his

father's hospitality. Improvement continued, and now, after one year, he says he is as well as ever.

Case 8.—Mr. Brown, aged about 60, consulted me in April, 1890. He is asthmatic, had the gripe a few months before and was left with a very aggravating cough. He had consulted three or four other physicians without benefit before he came to me. I prescribed an emulsion of eucalyptol and hyoscinum, and was gratified to hear from his own lips the next morning that he had spent the best night for several months. The cough ceased at once.

Case 9.—Mr. Adams, aged about 40. This patient first came into my hands in July, 1890. He was emaciated, had a consumptive look, complained of pain in both lungs, and coughed some in the morning. He had just buried a brother from consumption. His respirations were jerky and the area of hepatic flatness was enlarged. His greatest complaining was about a circumscribed point of tenderness in the greater curve of the stomach. This I believed to be a tubercular ulcer. I put this man upon eucalyptol and bismuth mixtures, in separate bottles, and kept him under observation for a few months; but as he would not believe there was anything wrong with his lungs, and as his stomach was not bettered, he desisted from the treatment. It is to be said, however, that the respirations nearly ceased to be jerky during the latter part of the time that he remained under treatment.

Case 10.—Mr. Hayt, aged 27, applied to me in January, 1891. He had had influenza and had been left in a condition of prostration, and with pain in both lungs. I found the respirations catchy and both lungs dull, especially in their lower portions. Strange to say the temperature was normal, the pulse 64, and the respiration 16. Four years before an eminent physician told him that something was wrong with his lungs. He had been obliged to quit work, and since had done but little work. He is about five feet and eleven inches tall and weighs only 135 pounds. He has a consumptive look. I put this man upon eucalyptol and cod-liver oil. Almost full resonance has been restored to the lungs and the respirations are but slightly interrupted. There never was any expectoration. My diagnosis in this case was chronic interstitial pneumonia.

Case 11.—Miss Taylor, aged 29. I was called to see this patient in January, 1891. She had had pneumonia in Grand Rapids, Michigan, and had come to her sister's a week earlier than her physician had told her she might. She took cold upon the train. This prevented resolution. I found her with a temperature of 101° and respirations 24. The lower lobe of the left lung was flat upon percussion, and the breathing was tubular. This was some two months after the onset of her pneumonia. The expectoration was muco-purulent and abundant. I prescribed eucalyptol and cod-liver oil for her. She has steadily improved and her prospects for an ultimate recovery are fairly good.

Case 12.—Miss Reid, aged 21. On the second day of March, 1891, I was called off from the road to see this girl. About Christmas time she was taken with the influenza. She partially recovered from this, and made two attempts to go back to school. Twice she failed, and twice went home. She was treated by another physician, and discharged as cured. Three or four days later I was called, as stated at the beginning of this paragraph, and found the following conditions: Temperature 103, pulse 130, respiration 24, free and muco-purulent expectoration, night-sweats, anorexia, and great prostration. Her respiration was catchy in both lungs, and accompanied by large and small moist râles on both sides. The percussion note was somewhat dulled on both sides, especially in the lower lobes. I believed that the girl had slid from the influenza into catarrhal pneumonia, and was likely to fall into acute miliary tuberculosis, and so informed the mother. I administered antipyretics and tonics, and later put her upon eucalyptol and cod-liver oil. A later examination of the

sputum revealed swarms of the bacillus tuberculosis. The case has been in my care now two months. The temperature averaged the first month about 102°; the second month 101°. The expectoration has grown much less. The respirations fell in two weeks to normal and have so remained ever since. The pulse has fallen from 130 to 90, where it stays. This may be normal for her, for the two grown sisters have the same rate of heart-beat, and they are perfectly well. Her appetite is returning and the bacilli have nearly disappeared from her sputa. The patient is still bedfast and in a precarious condition. Whatever the outcome may be, the fact is patent that the eucalyptol has done her much good. It looks as if it had averted the acute miliary tuberculosis, but also as if the patient were settling into a rapid phthisis, though no signs of cavities can be found, and no râles are now heard. The respiration has ceased to be catchy, and has become smooth in all the lung except in the upper lobe of the left lung, where it is harsh and tubular at this writing. It has been better here until a few days ago, when a sudden increase in the expectoration indicated the rupture of a tubercle. She has not menstruated for four months.

Case 13.—Mr. Allison, aged 20, came into my hands the first of April, 1891. This case is far gone with consumption. He had a temperature of 102°, pulse 110, and respirations 32. His expectoration was profuse and swarming with bacilli. He had night-sweats, tubular and jerky respiration in the left lung, pectoral pains, and was greatly emaciated. I had no expectation of producing any abiding change in the patient, but at once put him upon eucalyptol and cod-liver oil. In a fortnight his night sweats were stopped and the expectoration reduced one-half. The patient has been benefited by the treatment, but will die. He has had one hemorrhage since he has been in my care.

I am not putting eucalyptol forward as a specific for consumption, for it is not; but this experience has led me, as said in my opening paragraph, to put a high therapeutic value upon eucalyptol in persistent, irritable cough, chronic bronchitis, chronic interstitial pneumonia, and to a less degree in tuberculosis. Cases 1, 12 and 13 were certainly tubercular. There can be but little doubt that case 5 was tubercular. Five is well; there is some prospect that 12 will get well; 13 will die, and 1 is already dead. Case 7 was a case of gangrene of the lung, and is recovered. Cases 2, 3, 4, 6, 9 and 10 had symptoms of incipient phthisis. All are living, and in as good or better health than they were a year ago. Case 8 was a case of irritable cough. Case 10 is a case of chronic interstitial pneumonia. Eight is cured, and 10 is much improved.

Eucalyptol is very permeating. It is eliminated by the lung, the skin and the kidneys. It can be smelled upon the breath, upon the clothes when changed, and in the urine. It is antiseptic. It has a healing effect upon bronchial epithelium and a sedative effect upon the peripheral nerves in the respiratory tract. It is because of these physiological effects that the therapeutic results are produced.

I administer it in five to ten minim doses, in emulsion, every four hours.

THE THERAPEUTIC ACTION OF TONICA WATER. WITH THE HISTORY OF TWENTY-SIX CASES WHERE IT HAS BEEN USED.

Read at the Section of Practice of Medicine and Physiology, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1901.

BY J. W. SMALL, M.D.,

OF NEW YORK.

Water, as an agent in the treatment of disease, is a remedy which should not be too lightly estimated, as it is more or less concerned in all those changes which take place in inorganic matter, and is essential to the life and growth of all living organisms, whether animal or vegetable. When taken into the stomach it acts by its temperature, its bulk, its absorption, and as a solvent for mineral and vegetable matters which otherwise could produce no beneficial action in the animal economy. When natural spring waters are so far impregnated with foreign substances as to have a decided taste and a peculiar therapeutic action, they are classed in the Pharmacopœia as mineral waters, and are divided into five classes: the carbonated, alkaline, sulphuretted, saline (including magnesium, chalybeate and chlorinated), and silicious. The name of each of these classes suggests its peculiar impregnation; but analysis of the water of nearly all mineral springs shows a combination of the ingredients of two or more of these classes, and some, like the one I describe, the whole of them.

The Tonica mineral water is an alkaline, carbonated, sulphuretted, silicious, chalybeate water which comes from the earth in its natural purity at Highland Park, Conn., ten miles from Hartford, on the N. Y. and N. E. R. R. Its analysis, made at the Massachusetts Institute of Technology, shows it to contain to the U. S. gallon:

Sulphate of potassium	0.355 gr.
Carbonate of potassium	0.180 "
Chloride of sodium	0.215 "
Carbonate of sodium	0.345 "
Carbonate of lime	0.512 "
Carbonate of magnesium	0.234 "
Bicarbonate of iron	0.970 "
Phosphoric acid	0.051 "
Silica	0.618 "
Alumina	0.093 "
Oxide of manganese	a trace.
Sulphuretted hydrogen	a trace.
Organic and volatile matter	0.510 gr.

Making a total of 4.083 grs.

This water also contains carbonic acid gas in solution.

It will be seen from this analysis that the ingredient which enters most largely into its composition is bicarbonate of iron, of which each gallon contains 0.970 gr.; the next is silica, 0.618 gr.; and the third carbonate of lime, 0.512 gr. It also contains 0.051 gr. of phosphoric acid, a trace of oxide of manganese, sulphate and car-

bonate of potassium, and chloride and carbonate of sodium.

Therapeutic Action.—This water is not an active cathartic, but rather a mild aperient. By the stomach and bowels it is easily retained, absorbed and assimilated. It does not constipate the bowels, as do many of the waters which contain iron, and does not produce or increase acidity, being alkaline in its reaction. If taken in large quantity it will produce free catharsis at first, but its cathartic action diminishes with its use. It is at all times an active but gentle diuretic, increasing the frequency of micturition and the amount of urine excreted by the kidneys. It increases the appetite, promotes digestion, and gives a feeling of warmth, tonicity and buoyancy to the whole system. It has a slightly sulphurous, earthy but not unpleasant taste, and is readily taken by the most fastidious. But its most valuable therapeutic action is upon the blood, upon which it exerts all the beneficial effects of an iron tonic, without any of those disagreeable results which attend and follow the continued administration of iron in other forms. In all conditions of the system characterized by a depraved condition of the blood, as constitutional syphilis, scrofula, chronic albuminuria, phthisis, anemia and chlorosis, its revivifying action is soon apparent in the increasing bright, healthy color which it brings to the lips and cheeks, and its favorable action upon the appetite and digestion.

Mode of Administration.—In commencing the use of this water I have usually begun with a pint each day in divided doses taken before, during, or directly after meals, two or three times per day, and increased the amount gradually to one quart, and then diminished the quantity per day if the necessities of the case seemed to so require. In diabetic cases I usually commence with a quart or three pints and gradually diminish. If a quart is taken the first day it is usually followed by a free cathartic action of the bowels and free diuresis. But if a smaller quantity be taken at first and the amount gradually increased, only a gentle stimulation of the bowels and kidneys is perceived, and the same beneficial results are attained. In cases where wine is indicated, I give the wine with three or four times its quantity of the water, making a very pleasant and agreeable beverage. Upon my own table I always use it in this manner. It is also a very agreeable vehicle for bitter tinctures or infusions.

During the last year I have been enabled to make an extended use of this water in a large variety of chronic cases of disease, and also upon myself personally. In connection with three other physicians I have noted its use in about sixty cases. Only a few can be described in a paper like this, but I have selected twenty-six cases in which its use has been attended with the best results, and present their history herewith.

Case 1.—Chronic parenchymatous nephritis, cystitis and prostatitis. Mr. J. F. C., age 62 years. Contracted syphilis five years ago. Two years ago had syphilitic orchitis, resulting in sarcoma of right testicle, which was removed by a surgeon. When he came under my observation he was suffering from chronic parenchymatous nephritis, the amount of albumen in his urine being very large and containing fatty and hyaline casts. Also had chronic cystitis and catarrh of the bladder. Prostate gland very much enlarged and micturition impossible without the use of the catheter. Acute syphilitic orchitis of left testicle, which was enormously swollen. After the inflammatory symptoms had subsided I gave him Tonica water, directing him to drink an ordinary quart bottle full each day. At first it produced free catharsis and increased considerably the amount of urine excreted by the kidneys. At the end of one month marked improvement was visible, with albumen reduced one-half. At the end of two months albumen about one-fourth, and after three months one-eighth the original amount. Appetite and digestion improved from the first, so that instead of being confined to the house, he is now performing all the duties of an active business life. This patient had been unable to take any of the ordinary forms of iron on account of their constipating and irritating effects upon the bowels.

Case 2 —Obesity, gout and rheumatism. Mr. E. F., a clerk and a man of sedentary and indolent habits, age 50. Height 5 ft. 5 in., weight at commencement of treatment 220 lbs. Chest contained a large amount of fat, which materially weakened the action of the heart. Considerable dyspnoea upon slight exertion, as upon going up a long flight of stairs. Specific gravity of urine 1010, and contained considerable albumen. After some preliminary treatment, I gave Tonica water in doses of one pint each day, with meals, gradually increasing the amount to one quart each day and keeping it at the latter amount for one month, then gradually decreasing. At the end of one month all symptoms of gout and rheumatism were gone and albumen had disappeared from his urine. Weight reduced 10 lbs. Appetite and digestion were much improved and abnormal heart symptoms had disappeared. At the end of three months had lost 10 lbs. more in weight. It is now five months since I first ordered Tonica for this patient, and he has lost about 25 lbs. of flesh, while his general condition has improved very much. The only change I made in his diet was to order him to abstain from saccharine and amyloseous foods, tea and coffee, partake of but one course at a meal, and have plenty of exercise in the open air.

Case 3.—Obesity and membranous dysmenorrhoea. Mrs. E. B., housewife, age 45, height 5 ft. 4 in., weight 226 lbs. Heart sounds weak and

somewhat irregular, and great dyspnoea upon active exertion. Symptoms of fatty degeneration of muscular tissue of heart. Had suffered for two years from membranous dysmenorrhoea, the pain each month being intense and continuing from two to three days, and passage of membrane followed by very excessive menstrual flow. Gave a pint of Tonica each day, with injections into the uterine of sol. ac. carb. and tr. iodine once a week during the intermenstrual period, commencing first injection two days after cessation of menses. Regulated diet and exercise as in the preceding case. The result, after three months' treatment, has been a loss of 20 lbs. in weight, with complete cure of dysmenorrhoea. Condition of blood and general system very much improved.

Case 4.—Anemia, chronic bronchitis and asthma. Mrs. J. W., age 42, housekeeper, has suffered several years from chronic catarrh of nose and throat, chronic bronchitis, anemia and asthma. Applied local treatment to nose and throat and gave one pint Tonica each day for three months. At the end of that time the condition of this patient was very much better; catarrh and bronchitis wholly gone and no more attacks of asthma. Improvement in quality of blood very noticeable. I had previously given her iron in the form of a tincture and also a syrup of the albuminate, and combined with quinine and strychnine, but the effects were not lasting, as these seem to be.

Case 5.—Diabetes mellitus. Mr. E. R., age 40, engineer, had suffered for two years with gradual loss of weight, intense thirst and increased appetite. Former weight 180 lbs.; weight at beginning of treatment with Tonica 145 lbs. Amount of sugar in urine 13 grs. to oz. Specific gravity of urine 1042. I had previously limited this patient to a strict anti-diabetic diet and tried all the usual diabetic remedies, with the effect of reducing the specific gravity of the urine to 1037 and the amount of sugar somewhat, but not materially arresting the disease. In December, 1890, I commenced giving him Tonica water, giving him three pints each day and no other liquid, but continuing the anti-diabetic diet. At the end of January, 1891, I found the amount of sugar in the urine reduced to 5 grs. per oz. and specific gravity 1031, with marked diminution of thirst and appetite. March 3, I found the amount of sugar reduced to 3 grs. per oz., specific gravity 1029, with a gain in flesh of 10 lbs. At the present time (April 20, 1891), there is only a trace of sugar in the urine, its specific gravity is reduced to 1021; weight of patient is increased to 165 lbs.

Case 6.—Hypertrophy and valvular lesions of heart. Mr. R. W., 55 years old, shoe manufacturer, has taken a pint of Tonica each day for two months, with general improvement of blood and circulation, and disappearance of cardiac murmurs.

Case 7.—Anæmia and neurasthenia following "la grippe." Mr. J. R., artist, age 42, had a very severe attack of epidemic influenza, which was followed by general nervous weakness and anæmia. Gave one pint Tonica each day for two months. At the end of that time I find patient's general condition greatly improved, appetite and digestion good, and no remains of the malady apparent.

Case 8.—Anæmia and intercostal neuralgia. Mrs. E. F. J., age 43. Three years ago had two severe hæmorrhages from left lung. Has suffered since from anæmia with periodical attacks of intercostal neuralgia, these attacks occurring at intervals of a month or six weeks. Gave Tonica water, a pint each day for three months, with the effect of materially increasing the red corpuscles of the blood and improving the appetite and digestion. It has been now five months since I first gave this treatment, and for the last three months she has had no neuralgia.

Case 9.—Amenorrhœa, chlorosis. Emma B., age 16, had never menstruated, but had attacks of periodical headaches, recurring each month; is anæmic and poorly developed, skin yellow, complains of weakness and difficulty of breathing upon slight exertion, and shows symptoms of hypertrophy of heart. Gave one pint Tonica each day for three months, and ordered her to take plenty of exercise in the open air, with good nourishing diet, which soon established the menstrual flow, built up the blood and regulated the action of the heart and circulation.

Case 10.—Chronic dyspepsia, chronic constipation, acute rheumatism. Mrs. S. L., age 56, housewife, has had acid dyspepsia with troublesome flatulency for years, with occasional attacks of acute rheumatism. Is pale, anæmic, poorly nourished, and bowels constipated. Gave Tonica each day for three months, with disappearance of dyspeptic and rheumatic symptoms and general improvement of blood and digestion. Action of bowels, after once established, remains good.

In a paper written by R. M. Griswold, M.D., of Portland, Conn., a physician who lives in the vicinity of the springs and has had large opportunities for testing the medicinal qualities of the water, and entitled, "The Medicinal Use of Highland Tonica Water in various diseases, but especially in Dyspepsia and Diabetes Mellitus," I find a very interesting history of its use in thirteen cases, of which five were cases of chronic dyspepsia complicated with malaria and anæmia, one of acute malarial fever with acute gastritis, one of chronic cystitis, one of chronic eczema in a child 5 years old, and five cases of diabetes mellitus. Dr. Griswold claims such good results from the use of this water in these cases, and the history of the five cases of diabetes mellitus is so very interesting, that with his permission I have copied them from his valuable paper. Dr. Griswold says:

I will now notice five cases of diabetes mellitus treated with Tonica water after all other means of treatment had failed. In three of these cases the disease had not been even arrested by treatment. In the other two it had at times apparently been arrested, but there was no permanent improvement. Three of them, before coming under my observation, had been limited to the most approved anti-diabetic diet; the others had not been so strictly dieted. In all five cases the diagnosis was not to be doubted, as sugar in large amount was found in the urine repeatedly, both by physicians who had previously treated them, by myself, and by two experts in urinary analysis. The treatment in all these cases was similar, and consisted first, of a strictly anti-diabetic diet as follows: plain soups, oysters, clams, beef, poultry, bacon and ham, all kinds of vegetables except potatoes, turnips, carrots, parsnips, peas, beans and tomatoes. Cheese, butter, unsweetened custards, buttermilk, dry and sour wines, as claret and sherry, acid fruits, as lemons, currants, etc. Tea, cream, coffee without sugar, gluten bread from flour made by Farwell & Rhines, of Watertown, N. Y. In each case everything of a saccharine or farinaceous nature was carefully excluded, also all malt or spirituous liquors except the wines mentioned, and no water other than Tonica allowed. But it should be remembered that in three of these cases the diet had before been as carefully regulated, but with no apparent benefit.

Case 1.—Quarryman, 35 years old, Swede. Weighed when in health 190 lbs., present weight 130 lbs. Has been able to do no work for five months. Passes from 4 to 6 quarts of urine per day. Excessive thirst, markedly increased appetite. Pains in back, arms and legs, constant headache. Sugar 14 grs. to the oz., spec. gr. 1042. This case came under my observation in July, 1888. He was put upon red sulph. arsenic gr. 1-50 after meals, and limited to three pints of Tonica water per day for drink. At the end of one month a second examination of the urine showed sugar 5 grs. to the oz., sp. gr. 1032. In three months the amount of sugar was the same, and the sp. gr. had not decreased, but there was a marked diminution of thirst and desire for food, a slight gain in flesh, and improvement in the general condition. In five months the sugar had decreased to 2 grs. to the oz., and the sp. gr. to 1028, and there was a gain of 5 lbs. in flesh. From this time on the improvement was steady, and the gain in weight correspondingly so, and in April of the next year he resumed his work, when no sugar could be detected in his urine, although the sp. gr. still was above normal—1025. He had gained 25 lbs. in flesh and was apparently well. He remained under my observation until the autumn of 1890, when he returned to Sweden, at that time weighing 170 lbs.

Case 2.—In nearly every respect similar to Case 1, came under observation in September, 1888. Previous weight when in health 160 lbs., present weight 128 lbs. Amount of sugar in urine not noted, sp. gr. 1042. Treatment the same as in previous case. At the end of six months, sugar 3 grs. to the oz., sp. gr. 1031, gain in flesh 8 lbs. August, 1889, sugar 1/2 gr., sp. gr. 1028, gain in weight 13 lbs. Since that time I have examined the urine at intervals of about three months. At each examination traces of sugar are found, and the sp. gr. remains a little above normal, 1022 to 1026, but he feels well and maintains his present weight of about 150 lbs.

Case 3.—Quarryman, Swede, age 52. Previous weight 180 lbs., present weight 140 lbs. Not able to work for seven months. Came under observation January, 1890. Treatment as in previous cases. At time of first observation was passing 30 ozs. of urine per day. Sugar 20 grs. per oz., sp. gr. 1041. At last observation, January, 1891, he had gained 24 lbs. in flesh, sugar 3 grs. to oz., sp. gr. 1028. He is working every day and feels well.

Case 4.—Banker, aged 54. Had diabetes for six years. First seen in February, 1890. Weight seven years ago 102 lbs., present weight 142 lbs. No note of amount of sugar, sp. gr. 1038. Treatment as in previous cases. One

year from date, weight 165 lbs., sugar none, sp. gr. 1021. Case 5.—Merchant, age 47. Disease first diagnosed two years before. Came under observation March, 1890. Weight 124 lbs., previous weight 171 lbs. Sugar 14 grs. to oz., sp. gr. 1037. June, 1890, sugar 11 grs. to oz., sp. gr. 1031. September, 1890, sugar 4 grs. to oz., sp. gr. 1025, gain in weight 24 lbs.

Cases 3, 4 and 5 are still under observation. They are now, and have been for more than a year, using from one to three pints of Tonic water per day. In each case the arsenic was discontinued in from three to six months from the commencement of its use. The anti-diabetic diet is continued, but in each case I attribute the much more than usually favorable results to the Tonic water, as in each, but more especially in three of the cases, the same treatment had been faithfully followed for periods of from six months to six years, but without the Tonic, and in none of them had there been any improvement, and in all but two the disease was progressing rapidly to an apparently fatal termination.

My friend, Dr. James Tibbetts, of Hyde Park, Mass., has sent me the history of two cases of gout and rheumatism and one of chronic cystitis, in which he has used Tonic water very successfully, but for the sake of brevity I will omit the details.

At this date it does not require any argument to convince the medical profession of the utility and value of iron as a nutrient tonic for the blood. Of its peculiar action in anaemia Stillé says: "The red blood discs appear to be the organ to which iron is especially directed, and by which the activity of animal life as well as of organic life is sustained at the highest point. These bodies it is which by contact with the inspired air in the lungs attract and become impregnated with oxygen, the essential agent in all the compositions and decompositions which sustain life in the tissues, acquiring thereby the scarlet hue of arterial blood, which they lose with their oxygen in their passage through the tissues to the venous system. Thus it would appear that the activity of nutrition, and probably also of calorification, is dependent upon the iron in the blood; and that when the red blood discs which contain it are most abundant, all of the functions of the economy attain their highest degree of activity and vigor." And in his theory of the operation of iron he says: "Iron, on entering the blood-vessels, combines immediately with the discs which have not yet acquired or have lost more or less of their ferruginous element. It enters the blood as a chloride, is decomposed, combines with the discs as a carbonate of the protoxide of iron, and in the lungs gives up carbonic acid and absorbs oxygen, and is thereby converted into a peroxide. The white corpuscles are destitute of iron, but when once saturated with it neither they nor the red corpuscles can receive any more."

But in order to obtain in the system the effects of iron as a specific nutrient tonic it is necessary, in persons of a bilious temperament or those suffering from stomach or intestinal indigestion, or torpidity of the kidneys, to gently stimulate these organs, thereby increasing their activity and their

powers of absorption, assimilation and excretion, as, without a healthy action of these organs, most preparations of iron prove inert and act as a clog upon the system; and also to present the iron to the system in an exceedingly soluble condition, so that it may be easily absorbed and assimilated by the stomach and bowels.

Judging from my own experience with this water, it meets both these requirements more perfectly than any other ferruginous preparation which I have ever found, and for that reason is a most valuable adjuvant to other remedies in the treatment of:

1. Anæmia, amenorrhœa and chlorosis.
2. All menstrual derangements attended with periodical hæmorrhages.
3. In organic disease of the heart.
4. In nervous affections complicated with anæmia, as neuralgia, chorea, etc.
5. In depraved conditions of the blood, as constitutional syphilis, chronic albuminuria, and scrofula with anæmia.
6. In phthisis, chronic bronchitis and chronic catarrh.
7. As an alterative and nutrient tonic after eruptive fevers, as measles, scarlet fever, and in the anæmia following epidemic influenza.
8. In chronic malarial poisoning.
9. In errors of malassimilation and malnutrition, as diabetes mellitus, obesity, etc.
10. In chronic constipation complicated with acid dyspepsia and anæmia.

A REPORT OF THE EXPERIMENTS WITH TUBERCULIN AT THE GOOD SAMARITAN HOSPITAL IN CINCINNATI.

BY S. P. KRAMER, M.D.,
OF CINCINNATI, O.

The following is a report of the experiments with tuberculin in the treatment of tuberculosis, carried on in conjunction with Prof. Whitaker at the Good Samaritan Hospital in Cincinnati.

The work was begun on January 14th and has been continued up to the present time. Fifteen weeks' experience with the remedy is but a short time during which to gather material that shall give us definite results. This is offered as the result of observation during that time, to be taken for what it is worth.

I shall report only those cases in which the remedy was used systematically as treatment, leaving out the cases in which it was used for diagnostic purposes.

The injection of tuberculin, and nutritious diet and alcohol, constituted the only treatment used.

In all, then, there are twenty-nine cases. Two

of these were cases of tuberculosis of the lymphatic glands primarily. As they present many points of interest, I shall dwell on them somewhat in detail.

The first is the case of a young man, age 24. Since childhood he had suffered from repeated attacks of quinsy, and chronic inflammation of the tonsils and pharynx. Three years ago he began to be troubled with enlargement of the cervical lymphatics. This continued and led to the formation of three sinuses, which, when he was admitted, were discharging a slight quantity of thin serous fluid. Eighteen months ago he began to notice cough, with mucous expectoration. This was followed by night-sweats, hæmoptysis and loss of weight.

Examination revealed, besides the general enlargement of the cervical lymphatics, dullness on percussion, with rude inspiration and prolonged expiration over the right apex. Tubercle bacilli was found in the sputum.

The result here has been very satisfactory. The glands have diminished in size, cough and expectoration have disappeared, the patient has gained ten pounds in weight and the anaemia has been greatly ameliorated.

The other case is one of four years duration. The trouble began in the lymphatics of the right neck, extended to the left, involving the entire chain. About eighteen months ago there occurred an enlargement just beneath the left clavicle; it suppurated, was opened, and the sinus formed still remains. This sinus is found to communicate with a small cavity in the left apex. On forced expiration air escapes from the opening. With the exception of the left apex the lungs seem to be free from disease. The pulmonary symptoms began after the disease in the glands.

The progress in this case has been slow but appreciable. The glands have diminished in size. The cavity is diminishing in extent, the sides seemingly granulating and filling it up. After every dose of tuberculin the discharge from the sinus is increased in amount, in cellular elements and bacilli.

Both these cases illustrate the infection of the lungs and pulmonary lymphatics, from the lymphatics higher up. In the one the infection probably took place in the tonsils or pharynx.

The importance of attacking such cases in their incipency is self evident.

The remaining twenty-seven are cases of pulmonary disease. Of these, 17 were in the advanced stages, of the kind in which but little improvement is to be hoped for. Four of these have died; but neither clinically nor post-mortem was there any sign of an acute exacerbation, or that the treatment had hastened the end.

Ten have remained unchanged. That is, the natural course of the disease has not been influenced to any permanent degree.

Three of these cases show marked improvement. They have gained in weight, and strength. The cough and expectoration have diminished. Night-sweats have ceased and their general health has been improved. This is not due to the psychic effect. Because, as it has been our experience that all the cases do well for the first few weeks, cases have only been counted as improved in which the improvement has lasted beyond the first few weeks.

The other ten cases are cases in the first stage. That is, before signs of breaking down can be observed. Three of these remain unchanged. In these cases while there are no signs of cavities, yet the presence of considerable hectic, and chills, denote that the pus micrococci are responsible for a considerable part of the symptoms, and against these the fluid has no effect.

The remaining seven have all improved. They all show a marked diminution in cough, expectoration, and night sweats. The dullness of percussion still remains, but the bronchial catarrh has for the most part disappeared. The bacilli in the sputum have become less. They have gained in weight and strength.

Three of these cases have improved to a marked degree, and were it not for the fact that there still may be found an occasional bacillus by the Biedert method, they might be called cured.

We must, however, be very careful in speaking of the cure of tuberculosis. This is not accomplished in a few weeks, and relapses are the rule.

Thus it will be seen that the surgical and incipient cases do the best. Yet there are exceptions to the rule, and if we do our patients no harm, it is but just to give them the benefit of the doubt.

In regard to the diagnostic value of the remedy: This property of the fluid has been called in question of late. In judging of this point we must bear in mind that only a local reaction, a reaction at the seat of the disease, is of diagnostic value. A mere rise of temperature is of no value at all.

We must take a decided stand against the opinion that the use of the fluid is not justifiable for diagnostic purposes. On the contrary, as Prof. Koch has said, in the future the physician who fails to use it and thus neglects to give his patients the benefit of an early diagnosis will be guilty of gross negligence to say the least. One of the greatest sources of good will spring from this property of the fluid. For by its use alone will we be able to discover the very incipient stages of tubercular disease and then treat them to advantage.

In the use of the fluid we have observed certain contra indications and phenomena that are worthy of notice.

First, in regard to technique.

The Koch syringe has been adhered to as very

easily kept clean, and on account of the accuracy with which the dosage is obtained.

Second, as to dosage.

As a rule we begin 1 mg. and repeat this as often as it causes any rise of temperature whatever. The dose is then slowly increased 1 mg. at a time, avoiding all reaction. This plan has proven to be the wisest. The febrile reactions are not at all necessary, and they cannot but diminish the patient's strength. At first, before we saw the wisdom of this method, we had very severe reactions and the progress was very materially hindered.

By following the plan advised above, the patients by a careful and nutritious diet may be made to gain in weight from the beginning, which they will not do if severe reactions are produced. Indeed those cases have done the best in which there were scarcely any rise of temperature produced during the entire treatment.

The fluid seems to be contra-indicated in cases with intestinal complications. Clinically these cases do poorly, the diarrhoea is increased and the patients diminish in weight and vitality. Post-mortem examinations reveal that perforation is often rendered dangerously imminent, although few such accidents are on record.

In cases in which there is a considerable hectic, accompanied with chills, giving evidence that the complication is due to a septic process caused by the presence of the pus micrococci, the remedy does little if any good.

This, however, does not include all cases with an evening rise. Thus, I have repeatedly seen in patients where the evening temperature reached 101-102 before treatment, after a few weeks treatment the hectic disappears, there being no fever except that caused by the injection. Probably in these cases the fever was caused by the tubercular process and not by the entrance of the micrococci.

Hæmoptysis occurring during the treatment seems to indicate the remission of the remedy for a time. When we consider the histological changes caused by the fluid, the force of not producing an acute congestion in these cases strikes us at once. This complication occurred in one of our patients. The treatment was remitted for two weeks and the hæmorrhage not recurring, the treatment was resumed. There was no further hæmorrhage and the progress of the case is favorable.

Perhaps it would be wise in all cases to remit the treatment for a week at a time occasionally, sending the patient from the hospital. We have noticed the efficacy of this in a number of cases.

The following is a case showing the extreme irregularity of the action of the remedy. The patient is a woman of thirty, pulmonary tuberculosis, primary stage, at the left apex.

On January 25, the first injection of 2 mg. was

given; no reaction. January 27, 5 mg.; marked local reaction, cough, dyspnoea, chill, temperature 102½.

January 29, 5 mg.; local reaction slight, temperature 100½.

After this the dosage was gradually increased to 4½ cg. on February 15. At no time during this period was there any reaction. February 18, 6 cg. were given and there followed a very sharp reaction indeed, marked dyspnoea, cough, nausea, and vomiting; temperature 104. The next day the temperature had fallen to the normal, expectoration being greatly increased and bacilli more numerous. February 21, 5 cg.; no reaction. February 23, 6 cg.; no reaction.

As seen from the above report we cannot be too careful in increasing the dose even though the reactions be not present.

And now a few remarks as to the opinion in the minds of the profession and laity as to the efficacy of the treatment.

The pendulum has swung to the other side and unlike the mechanical pendulum it has perhaps gone further to the left than to the right. But like its mathematical brother it will swing back and continue to oscillate until it comes to its true point, to the calm and quiet of the middle line. Let me seriously warn against throwing the remedy away. It is too early, we have not had sufficient time to pass final judgment. The most careful observation and study of years will alone give us that.

That the remedy is a specific against tubercular disease no one who has seen its action in a case of lupus will doubt. In so far as regards the science of medicine, the specific character of the remedy may be considered a settled fact. The cure of one case of lupus is sufficient evidence for this.

Everything else, the determination of suitable cases, surgical aid, prevention of accident, are details to be settled by the physician's art. As Professor Koch said, "In all cases, the art of the physician must be allowed free scope in that we shall carefully individualize, and all means known to the physician or surgeon shall be brought to the aid of the remedy."

This is not to be done in a day. We have but to remember our experience with mercury and iodine as specifics against lues. These remedies have been known to medicine for centuries, but it is only within the present generation that we have learned the proper use of them. Perhaps the full benefits of the remedy will be scarcely felt by the present generation.

To continue the above analogy: May it not occur that the history of tuberculosis in the course of a century will undergo the same change? That the disease will lose much of its virulence and that the advanced cases with such extreme destruction of tissue will become a rare occurrence?

This is what we must look forward to and aid with all our powers as physicians.

The objection has been raised that the treatment has in some cases caused a spreading of the disease and acute tuberculosis. Liebmman has stated that he has found tubercle bacilli in the blood of patients treated with the fluid. These examinations have been repeated by Professors Ewale and Guttman in a number of cases, and no bacilli found. A careful examination of Lippmann's slides have revealed the fact that the glasses used contained traces of old sputum. They had not been sufficiently cleaned.

To the charge that the fluid contained tubercle bacilli, and that we were in danger of giving our patients acute tuberculosis by its use, Dr. Libbertz has replied that there were a few tubercle bacilli in the preparation, but that they had been killed by repeated boiling.

Inoculation experiments have confirmed this statement.

The injection of 2 cc. under the skin of the speaker gave rise to the following symptoms:

Four hours after the injection of 2 cc. under the skin of the left forearm, I experienced severe headache, backache, malaise and nausea. The temperature rose to 99.8, pulse full, 108. The rate of breathing was also increased to about 30. These symptoms continued for four hours, when the thermometer registered 98. That night I slept comfortably; the following morning the arm was sore and tender and swollen. There developed a lymphangitis which lasted for 48 hours. During this time the thermometer reached 102. I suffered from severe headache and malaise. The trouble subsided, however, leaving absolutely no symptoms whatsoever. The effect of the fluid had passed off after twelve hours. The subsequent lymphangitis I attribute to the fact that the syringe used was not sterilized, and secondly that the forearm was not a well chosen place for the injection.

I have learned these points from this experience:

1. To adhere to the Koch syringe, rather than the ordinary hypodermic which I had used in my own case.

2. To appreciate the wisdom of Koch's recommendation to use the interscapular region as the site of the injection.

3. That the injection of tuberculin does not produce any deleterious effects in healthy people. I would like to state that mine was the only case in my experience in which there occurred any trouble at the site of the injection.

Perhaps in a number of cases where acute tuberculosis was found, the remedy had lighted up a number of latent tubercular points, rather than that they had been produced by a scattering of the bacilli from the older lesions. Further study and observation may lead us to avoid such cases

in the future. Above all, we are to remember the work and instruction of Professor Koch, and that the chapter on the treatment of tuberculosis is not a closed one by any means.

ON THE CHARACTER OF THE EVIDENCE AS TO THE INJURIOUSNESS OF ARSENIC AS A DOMESTIC POISON.

Read in the Section of Practice of Medicine and Physiology, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May 5-8, 1891.

BY JAMES J. PUTNAM, M.D.,
OF BOSTON, MASS.

This communication is an attempt to place in as clear a light as possible, the credibility of the evidence that symptoms of arsenical poison may occur as a result of the ordinary exposures, such as are met with in domestic or civic life.

I shall not try to indicate the frequency with which such poisoning occurs, but only the possibility that it may occur; for the question as to frequency can only be satisfactorily answered when a large body of facts have been accumulated, especially those relating to the obscurer forms of chronic poisoning. The first thing to be done, would seem to be to disprove the opinion which has so much weight, even among those who would otherwise credit the evidence of domestic poisoning, that not enough arsenic could possibly reach the tissues to cause serious effects.

For this purpose I shall show: first, that urine analyses indicate beyond cavil that the exposures of civic life are a very frequent cause of arsenical contamination; next, that our knowledge of the laws of elimination indicates that the excretion of the small quantities which pass off with the urine day after day for months and years, in the case of many persons in the community, implies the presence by accumulation of much larger quantities in the tissues. The dangers attending domestic exposure might, in fact, be fairly compared with the dangers attending the medical use of arsenic, and I shall show that these dangers are usually underestimated. If in the cases of domestic exposure, the single doses are smaller, yet on the other hand, the period of exposure is much greater; the patient is not under the watchful care of a physician; the character of the arsenical compounds sometimes brings special dangers; the place of absorption is often the lungs and not the stomach; and there is some reason to believe, that there are certain very chronic and exceptional forms of poisoning, following the repeated use of minute doses, with which we are not yet thoroughly familiar, and which, in the absence of signs of acute poisoning, are likely to be overlooked.

The dangers attending the medicinal use of arsenic have been underestimated by physicians, partly because of their relative infrequency; partly because the first indications of them (œdema of the face, irritation of the mucous membranes, etc.) are so familiar, and usually so amenable to treatment, that they are hardly looked upon for what they are, namely, imperative signs that symptoms of more serious import are not far off (as shown by the experiments of Vaudrey).

Again, the effects of habituation, the storage of the arsenic in a temporarily innocuous form (albuminoid compounds of arsenic; Dogiel, International Congress, Copenhagen, 1886), and constitutional indifference to the poison confer as a rule such complete immunity, that those not so fully protected by nature, or with whom the protection ceases after a time, for one or another cause, stand in all the greater danger on account of the false impression of security which is spread abroad, and which makes physicians impatient of studying the obscurer indications of poisoning.

The most important collateral facts bearing on the question of the quantity of arsenic absorbed in domestic poisoning cases, are, as above stated, those obtained by urine analyses, of which large numbers have been made by the chemists associated with Harvard University.¹

To speak of only the most recent and conclusive series of experiments, Dr. C. P. Worcester, of Harvard University, a skilled chemist and with large experience in this particular analysis, has examined for my brother and myself one hundred and fifty urines, taken from patients most of whom presented certain obscure symptoms, but not such as would have justified the diagnosis of arsenical poisoning, and has found arsenic in more than thirty per cent., in quantities varying from a trace to upwards of .05 mg. to the litre.

About half of these patients were private, while the other half were from the clinic for Diseases of the Nervous System of the Massachusetts General Hospital, and many of the latter were chosen as presenting no arsenical symptoms.

These results conclusively show: *first*, that the community is exposed to arsenical contamination on a very large scale, so that the occasional occurrence of poisoning, due perhaps to special susceptibility, unusual exposure, failure of elimination, etc., need occasion no surprise, and ought to be carefully sought for by every physician; *second*, that the mere finding of arsenic in the urine in a doubtful case does not prove that the symptoms were of arsenical origin.

What does the elimination of these small quantities indicate as to the amount present in the tissues?

It was formerly believed that arsenic differed from lead in being eliminated rapidly and in not uniting with the tissues. Both of these opinions are now disproved. Arsenic has been found in the liver bones (Gibbs) six months after the cessation of a course of arsenical treatment (which, by the way, led to the patient's death); it has been found in the urine even nine months after the apparent removal of the patients from exposure in "domestic" cases; and Prof. E. S. Wood has recently found traces in the urine as long as three months after cessation of a short course of arsenical treatment (these experiments are not yet concluded, and I quote a verbal statement only as relating to one or two cases).

Arsenic does then, in some cases at least, tend to accumulate, and the daily elimination of .03 to .3 mg. (gr. $\frac{2}{1000}$ to $\frac{3}{1000}$, computed by supposing two litres of urine to be excreted daily, and to contain two-thirds of the whole elimination of the arsenic), must indicate the presence in the tissues of quantities quite large enough to cause poisoning, provided it should become active all at once, or provided that for any reason the elimination should be checked.

That the effects of arsenic—like those of lead, and phosphorus—are in a measure dependent upon the action of the stored up poison, is shown by the fact that the symptoms of medicinal poisoning often appear only when a given dose has been taken for some time, after which the patient is apt to show an increased sensitiveness (though this is not regularly the case). In the case of lead it is a matter of common knowledge that sudden outbreaks may occur after lead drinking water has been used for a long time, as well as among the workers in lead mines. In the case of arsenic, it is quite common to find the paralytic symptoms breaking out days or weeks after a single large dose or repeated smaller doses.

Is the use of arsenic in maximum therapeutic doses unattended with danger?

This is by no means the case, although the doses used are far less, at their largest, than those taken by the Styrian peasants with impunity.

Habituation to large doses may by care be brought about, but in the attempt to do this the lesser symptoms of poisoning are frequently excited, and the graver symptoms occasionally.

No doubt there are but few physicians who have had these graver symptoms in their own practice, but this is certainly because they have taken pains to avoid them, for the experiments of Vaudrey upon himself and others, have shown that by increasing a little further the doses which excite the lighter symptoms, serious prostration and local symptoms regularly follow. A few years ago I collected a number of the severer cases of medicinal poisoning, and I give here a few of them in brief outline. The cases of

¹ Especially Profs. E. S. Wood, C. Harrington, W. B. Hills, C. R. Sanger, now of Annapolis Naval Academy, H. B. Hill, C. P. Worcester, A. M. Corney.

² Boston Medical and Surgical Journal, March, 1888.

paralysis are especially noteworthy because these are now known to occur frequently in arsenical poisoning of a certain grade, and, as we shall see, they reappear among the cases of "domestic" poisoning.

1. Gaillard: Typical arsenical paralysis following full doses of Fowler's solution, increased to the limits of tolerance and administered for five weeks.

2. Canada Med. and Surg. Journ., 1886-1887, v. 15, p. 716. Arsenical paralysis, ending fatally, after large doses ($\mathcal{M}\text{xx}$ to xxx) of Fowler's solution. The autopsy showed the presence of neuritis.

3. Hastings: Arsenical paralysis with neuritic symptoms, following $\mathcal{M}\text{ij}$ to v of Fowler's solution continued for some weeks.

4. Gibb: Long course of arsenical treatment ending in neuritis, causing disorders of sensibility, pain, and paralysis. The patient died six months later, having taken no arsenic in the interval, and traces of arsenic were found in the liver and bones.

5. Dublin Quarterly Jr., v. 36, p. 474. $\mathcal{M}\text{ij}$ of Fowler's solution, were taken daily for ten or twelve months, at the end of which time "symptoms of acute arsenical poisoning" came on, ending rapidly in death.

6. C. L. Dana: Arsenical paresis with ataxia. $\mathcal{M}\text{xxx}$ of Fowler's solution three times daily, in spite of the fact that the dose had been gradually increased.

7. Hooper: $\mathcal{M}\text{v}$ of Fowler's solution were given three times daily for eight months. Toward the end of this time the following symptoms came on and increased, ending three months later in death: conjunctivitis with oedema, tachycardia, tremor, excessive and progressive prostration, insomnia, irritation of the trachea and larynx.

8. Jones: $\mathcal{M}\text{v}$ to xv of liquor arsenicalis given three times daily; at the end of a month, intense gastro-intestinal irritation, scanty urine, trophic changes in the legs, sensory and motor paresis.

9. Burne, cited by Taylor: Gr. $\frac{3}{4}$ of arsenious acid daily for four days; then, inflammation of the stomach, delirium, debility and exhaustion.

10. Taylor: Gr. $\frac{3}{4}$ of arsenious acid taken twice daily for seven days, then, "sickness," irritation of the skin, and eczema over the whole body.

11. Taylor: $\mathcal{M}\text{x}$ of liquor arsenicalis chloridi (said to be a very poisonous preparation) taken three times in the course of twenty-four hours; then, constriction in the throat, pain and irritation of the stomach and bowels, tingling and

numbness of the hands and feet, with paresis; extreme depression; gradual recovery.

12. Personal Observation: $\mathcal{M}\text{iv}$ to v of Fowler's solution taken three times daily for six weeks; then there came on extreme prostration, pains of severe character in the extremities, widespread muscular atrophy, and paralysis, so severe that the patient was helpless for many months. During the worst of his illness he inhabited a room with a highly arsenical paper. I consider this case as especially important because it was possible to eliminate, as satisfactorily as this can ever be done, all the other causes of neuritis. The patient was a gentleman in good circumstances, not syphilitic, not tuberculous, with no lead in the urine. He had had no acute diseases, no grippe, no anæmia; and the symptoms came on during the pleasant weather of June.

Of course this handful of cases does not prove that arsenical paralysis is common from medicinal doses, but only that it occurs.

There are, however, three obvious reasons why we do not have more such reports: 1. The watchfulness of physicians; 2. The failure to recognize the nature of the cases seen; 3. Unwillingness to report unfavorable results.

Imbert Gourbeyre says that many cases of paralysis occurred in the last century when arsenic was used so freely in the treatment of intermittent fever. He does not give references, however, and I have not yet fully studied this point.

Dr. Winkler, of Altenburg, writing in 1811, quaintly reports a case of paralysis of the legs occurring in the practice of a colleague, after an arsenical treatment of intermittent, but "does not believe" it was due to arsenic, and is obviously wholly unfamiliar with the characteristics of arsenical paralysis, now so well known.

This would be a suitable place to introduce, by way of comparison, the recorded cases of paralysis due to domestic exposures.

I have not, however, undertaken, in this paper, to bring forward the clinical evidence indicating the frequency with which arsenical symptoms occur, but only such as would present as strongly as possible the fact that they do occur.

For this reason I shall confine myself to my own experience in speaking of arsenical paralysis (and other signs of neuritis). I will note, however, that a number of such cases are on record. Alexander, of Breslau,¹ for example, in a recent pathological monograph on arsenical paralysis (1889), considers nine cases to have been of "domestic" origin, out of fifty-eight which he selected from a much larger number of general analysis.

The cases which I have seen myself, several in number, were mainly light cases, as might be expected, and for that reason less conclusive. I

¹ It has been abundantly shown by the history of acute arsenical poisoning that symptoms once inaugurated may continue and increase, though no more arsenic is taken. The paralysis, for example, often fails to appear for days or weeks, and even months

¹ Boston Medical and Surgical Journal, March 7, 1889.

therefore report but two, one of which has been published.* (Atwood.) This is the case of a lady 43 years old, and of naturally good health, except that for a year or two she had suffered from severe colds and from "indigestion."

The new symptoms began about six weeks after her return from a vacation, at which time she had moved into new rooms, which were afterwards found to be papered with a highly arsenical paper.

The symptoms consisted, first, in severe abdominal neuralgia, recurring every morning and passing away in the afternoon, and not attended with signs of indigestion. This continued for nine months, but before the end of this period she began to lose sleep and appetite, and to notice tingling sensations in the fingers, lips, tongue and feet. The hands and wrists became sensitive on pressure, and whenever she was recumbent the arms used to "go to sleep." Writing, formerly easy, became a labor.

The dynamometer registered R. 55. L. 17, instead of 30 to 50 as might have been expected; hyperextension of the right hand and fingers was very poor; there was tremor of both hands; the electrical reactions of the extensors, especially those of the right arm, were markedly impaired.

The patient has been under observation for the past two years, and had been known to me for several years before. Arsenic (but no lead) was found in the urine three or four times at intervals of many months, at first in relatively large amounts, afterwards in traces, until finally it disappeared.

The health gradually improved after removal from exposure, except that a moderately severe facial spasm has been present ever since. The general health has once or twice given way to some extent under hard work, but the special symptoms have never returned. I omitted to say that at one time the sensibility of the right finger tips was found slightly less than that of the left. The dynamometer finally registered

R. 35.
L. 35.

I consider this case of special value for the reason that while evidently an instance of neuritis, the morbid conditions would certainly have been overlooked but for careful examination. Careful electrical examinations in doubtful cases would very likely reveal slight changes of great diagnostic importance, since we know, both from experimentation with animals, and from clinical observation, with both lead and arsenic, that there is a period when neuritis is latent as regards paralysis, and yet is discoverable by electrical tests and by the microscope.

Far more numerous than these characteristic cases of arsenical neuritis, are of course the lesser

and obscurer symptoms, and they are also really of far greater importance just because they are obscure. I shall not occupy space by discussing them, because physicians at large are not yet in the mood to consider them without prejudice, and my present object is solely to allay that prejudice. I will only remark that we have good reason to believe, not only from the history of domestic poisoning, but from medicinal, and accidental, and homicidal cases, that in chronic arsenical poisoning, or in the chronic remains of acute poisoning, two tendencies are occasionally manifest; one to relatively isolated impairment of special organs or functions—tachycardia, sexual impotence, loss of voice, irritation of the kidney, localized neuralgia, herpes zoster and other affection of the skin, etc.; the other to anemia, or the impairment of the general nutrition, without marked local symptoms.

This latter tendency has seemed to me especially important as occurring among infants. I have, however, also seen, in consultation, in a child of two years, a generalized neuritis, with impairment of the electrical reactions, apparently due to arsenical poisoning. What is the source of the arsenic in the cases of domestic poisoning; and in what form does it act?

These questions are still unanswered, but no candid person can doubt that papers (mainly those of older date) and fabrics are mainly responsible. Probably it comes little by little from many sources and acts after accumulation. In the case of a lady, under my own care, a severe eruption, of inflammatory vesicular character, broke out all over the face and neck. She was seen by an experienced dermatologist who pronounced the eruption not eczematous, and found traces of arsenic in the scales removed from the skin. I found traces of arsenic in the urine and a large quantity in the covering of a reclining chair in which she habitually sat. The patient was subject to universal eczema, and had proved susceptible to arsenic given internally. Perhaps for these reasons the skin was unusually sensitive.

The theory that the arsenic sometimes occurs in a gaseous form cannot yet be set aside; and the mode of introduction (i. e., by the lungs) may perhaps increase its immediate violence, just as Alexander (l.c.) found that when injected under the skin of the shoulder in animals it had more constitutional effect than when injected into the peritoneal cavity. At any rate, the urine analyses prove that it comes from somewhere and accumulates in quite a quantity; and the clinical analyses prove that it may cause serious and characteristic symptoms, and a great many more slight but very troublesome and often chronic and obscure effects.

For details see the published report Boston Medical and Surgical Journal March 7, 1889.

MEDICAL PROGRESS.

obstetrics and Diseases of Women.

DANGERS OF VAGINAL INJECTIONS.—DR. ROULIN, (*Journal de Médecine de Paris*, December 13, 1890), describes three cases where women suffered from severe symptoms after the use of vaginal injections, administered by themselves when in a sitting position. The first used the douche can,—fixing it rather high on the wall. Immediately after the injection violent hypogastric and lumbar pains set in, followed by vertigo and vomiting. The abdomen was not sensitive on pressure, though the pain was intense. Metrorrhagia followed and lasted for two or three days, but the pain ceased in twenty-four hours. The second case was almost precisely similar, excepting that the patient had used a hand syringe, and the symptoms were less severe. The third case also used a hand syringe. She felt a pain like a blow across the belly, but continued the injection; when it was ended lumbar and abdominal pains came on severely with rigors and chattering of the teeth, but no vomiting. The symptoms recurred on the next day when the patient got up, but on the third day she felt well and free from pain. Dr. Roulin employs laudanum enemata for these cases. The cause of the pain is obscure. The fluid rushing into the uterine cavity may act as a foreign body and set up conditions sometimes provoked by catheterism. The admission of air into the uterine sinuses has been, according to Depaul, the cause of sudden death during douching of the cervix to produce abortion. Dr. Roulin believes that water may have entered in his cases. He insists that patients must be taught how to administer vaginal injections to themselves. The patient must lie on her back and only introduce the nozzle for a short distance; nor must she play too strong a jet of fluid into the vagina.—*Archives of Gynecology*.

Pathology.

THE PIGMENT OF MELANOSIS.—DR. FELIX LAGRANGE, in a paper read before the Société d'Anatomie et de Physiologie de Bordeaux, Dec. 8 of last year, described some investigations he had made as regards the distribution of the pigment in two melanotic tumors. One case was that of a melanotic sarcoma which had been removed from the orbit, and the other was a tumor of the eyelid. Microscopic examination showed the same structure in both cases, but the tumor which had developed in the orbit was more deeply pigmented than the other, though the distribution of the pigment was morphologically the same in each case. Sections of both tumors exhibited fusiform cells and many embryonic elements. A few vessels were seen, but there were no hemorrhagic foci. The pigment was intracellular. In some cells it was completely absent,

whilst others were so full as to lose their characteristics, and to appear as black round masses; other cells, again, contained in their protoplasm fine black granules. In order to study the nature of this pigment it was necessary to isolate it from the cellular elements. By treating a section with sulphuric acid, the cellular elements were partially destroyed. Under the influence of this reagent the sarcomatous tissue became shrivelled, remaining as a translucent structureless mass, in the centre of which was the pigment. Nitric acid was next tried; but, although the structure of the tumor was completely destroyed, there still remained a whitish residue in which the pigment remained entangled. In order to obtain a pure preparation of melanine the following process was adopted with success: Having treated a portion of the tumor in which the pigment was abundant with pure sulphuric acid, it was placed, still saturated with the reagent, for twenty-four hours in a moist chamber. In this way the now plastic tissue was partially liquefied, some glycerine was then added, and the containing vessel closed for forty-eight hours. At the end of that period there remained nothing but the pure pigment. It presented three principal forms: 1. Some black masses, evidently formed by the union of a series of granules, separated by unequal intervals, the spaces being filled by a transparent cement which had been unaffected by the acid. These masses were the remains of those cells which had appeared to be entirely filled with pigment. 2. Fine disseminated granules, which were rounded and very numerous. 3. Small irregularly shaped particles, for the most part angular, but presenting considerable variations in their form and size.—*The Lancet*.

Dermatology.

DR. L. BROcq (*Journ. of Cutan. and Genito-Urin. Dis.*, No. 102, March, 1891), presented to the French Society of Dermatology and Syphilography, December 11, 1890, a patient affected with a band of scleroderma extending from the upper third of the right arm to the thumb, forming a *plaque* 3 to 6 centimetres in width, and of great thickness. The patient, a cutter, could use his scissors only with great pain. Treated by Dr. Besnier in several ways without result, he was referred to Dr. Brocq in June, 1890, who up to December 1, gave him fourteen sittings of electrolysis, each treatment comprising twelve to sixteen punctures, principally in the lower portion of the *plaque*, but sometimes in the median portion. The affection was arrested and has not since increased. The arm moves more freely and the *plaque* has diminished one-half. Treatment was interrupted through August and September, but the affection did not increase, thus proving that it is not necessary to make the sittings close together.—*British Medical Journal*.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the *Treasurer*, Richard J. Duglison, M. D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, MAY 30, 1891.

YOUR MANUSCRIPT, PLEASE.

The primary province of this journal is to publish the proceedings of the annual meetings of the American Medical Association, and in order that all the members and readers of THE JOURNAL may see the papers and discussions at the earliest possible date, it is necessary that the Chairmen and Secretaries of each of the Sections shall at once transmit to the Editor of THE JOURNAL all matter in their hands for publication.

If this is done immediately, it will enable us to publish all the matter of each Section in consecutive issues, and then to make a separate reprint of the work of the several Sections for the special use of those who attended the meeting and are recorded as taking part in the Section work.

This will add very much to the value and interest taken in a work that should reflect the thought, observations and researches of many of the ablest men in our profession.

The success of the purpose will depend entirely upon the active coöperation of the officers of the Sections.

We want all the matter now, while it is fresh and of immediate interest.

The member who is holding his paper for revision and completion, and is also possessed of an idea that the adoption of such a plan will cause an early shortness of copy in THE JOURNAL office, is away off in his estimate of the amount of scintillations that are constantly emanating from the brains of more than eighty thousand practicing physicians.

BUSINESS.

Business is business, at least that is what all business men say, and the merchant, manufacturer, trader or professional man who can in one year double the value of his business by making a grand effort and don't do it, is usually regarded either as a little off, or entirely too slow to catch on to the good things that are gliding by on a rapid transit motor.

There is in this country a grand body of more than eighty thousand members of the regular medical profession, every one of whom is in some degree a debtor to the American Medical Association, and either directly or indirectly claims an affiliation with this organization. Those who directly claim the benefits have become permanent members. This number has now reached six thousand. These six thousand members own a valuable property in this Journal, each holding a single share of stock and no more. It is possible and very easy, for every one of the six thousand shareholders to induce one of the indirect beneficiaries to become enrolled as an active owner of this valuable property. The simple addition of six thousand more members will very much more than double the value of the present property, and another possible and similar increase will send THE JOURNAL ahead and beyond any similar publication in the world.

This is a reasonable and easy thing to do. Not to do it is to be counted a "little off" and too slow to take advantage of a good thing within easy reach.

This is business, and business is business.

HOUSE BUILDING AND SANITATION.

With the growth of population in cities there is a corresponding increase in the value of real property. This increased value of real estate is naturally followed by high rents, and in order to realize the largest possible revenue from a limited number of square feet of ground, the owner feels justified in erecting a building that is fairly a sky-scraper. And this without the slightest regard for the rights of his next door neighbor or the general public. Such buildings effectually darken adjacent structures by shutting off a goodly portion of God-given sun-light. They also impede a free circulation of air.

In the out-kirts of the business section, elegant and inviting apartment houses are built, and in which are said to be found all modern conveniences, such as bath, water-closet, etc. These are necessary belongings in every modern city house, and in order to insure the health of the inmates, the location and construction of the plumbing work of such apartments is of the very first importance.

Our attention has been drawn in this direction by observing the great frequency with which the water-closet is stuck in an absolutely dark and unventilated niche or corner, and in many instances opening directly into the kitchen or pantry. Physicians visiting patients may with perfect propriety inquire as to the arrangement of the bath and water closet, and condemn or approve as his judgment may dictate. Many cases of sickness are directly traceable to just such causes.

One of the building inspectors should be a physician who is not only skilled in sanitary affairs, but who is also endowed with a knowledge of architecture so far as it pertains to all sanitary conditions of any building.

Practicing physicians are more or less accustomed to uninviting sights and noisome odors, but, for one moment think a little,—just a very little of the wafting odors of a freely used and unventilated water closet opening into a kitchen where an omelet, or batter for griddle cakes are being prepared; or into the pantry where the butter and milk are acting as sponges in silently mopping up the foulness in the air.—Bah!

THE MEDICAL CONGRESS OF CUBA.

The second Medical Congress of Cuba will be held in Havana in January, 1892, under the presidency of DR. JUAN SARTOS FERNANDEZ. This new organization is one of very high order and represents the strongest professional elements of the country. The published regulations show that the qualifications for membership are very high, requiring in addition to medical graduation, the possession of either an academic degree or the record of original work meriting the approbation of the Congress. The Congress meets every two years in the month of January. Papers are limited to fifteen minutes and discussion to five minutes for each speaker. Papers may be read in Spanish, French, or English.

The preliminary program announced for next meeting shows an important selection of topics. "The Etiology, Prophylaxis and Treatment of Yellow Fever," is an inexhaustible theme for Cubans. "The Influence of Malaria upon Pregnancy, Parturition and the Puerperium," is a subject of vast importance, not only to peoples of the tropics, but to the inhabitants of peludal districts in the temperate zones. "The Experimental and Clinical Study of Chronic Diarrhoea" will doubtless comprise a report of value to all practitioners. "The Abuse of Alcoholic Beverages in Cuba" will no doubt elicit about the same state of affairs that we find in this country, particularly when the subject is studied as is purposed with reference to "common causes and pathological manifestations." "The Pathology of Diphtheria and its Relation to Treatment" suggests a theme in rational therapeutics that is of wide-spread interest. In addition to such formal discussions papers will be presented on topics in every department of medical practice. The practice of announcing subjects for discussion ten months in advance of the meeting is a good one, and might be emulated with profit by medical associations in the United States.

HIGHER MEDICAL EDUCATION.

At a meeting of the Board of Trustees of the University of Pennsylvania held May 21, Dr Pepper made an offer of \$50,000 towards an endowment fund of \$250,000 and of \$1,000 annually towards a guarantee fund of \$20,000 annually, for five years, conditioned upon the establishment of an obligatory graded four year course of medical study. This was accompanied by a communication from the medical faculty pledging themselves to carry out this proposal and to enter upon the four-year course in September, 1893. It was also reported that the members of the medical faculty had themselves subscribed \$10,000 annually for five years to the endowment fund. The Board of Trustees expressed approval of the proposed advance in medical education, but postponed their assent until the success of both funds had been demonstrated.

DR. PEPPER and his associates in the faculty of the medical department of the University of Pennsylvania are evidently determined to do their part in solving the vexed question as to the best method of giving and attaining a higher medical education. It is with a good degree of pleasure that we note the disposition manifested on the

part of the best medical colleges to form practical connections with established universities. This is the first step necessary, before making an appeal for endowments of chairs, scholarships, and laboratories.

The medical department of a University with an ample endowment, ensures a proper preliminary examination, a thorough course of instruction, followed by the granting of a degree that means something.

EDITORIAL NOTES.

SMALL-POX IN HAVANA.—The last issue of the *Revista de Ciencias Médicas* of Havana announces fifteen deaths from small-pox in that city during the month of April. Dr. Lagnardia, of the Sanitary Department, announces that the disease is spreading.

HIGH BUILDINGS.—We are glad to observe that a discussion is going on among the architects and engineers of Chicago, relative to the safety of the extremely high buildings which are in course of construction in this and other large cities. This is a subject of the utmost conceivable importance. The fall of such a structure when filled with an army of workers would be a calamity of the greatest magnitude.

While we are ever ready to utter an encouraging word to those who are engaged in all laudable enterprises, profound consideration must be given to any conditions which jeopardize and hazard human life.

The sanitary arrangements of such buildings are usually first class and as perfect as art can make them.

SOCIETY PROCEEDINGS.

American Academy of Medicine.

The sixteenth annual meeting of the American Academy of Medicine was held at the Arlington Hotel, Washington. The opening session was on Saturday, May 2, the meeting continuing through Monday the 4th. The wisdom of holding the sessions of the Academy in connection with those of the American Medical Association was demonstrated by the attendance: it was the largest meeting in the last seven years. The attention of the Fellows was directed to those three items, the Reports of Committees, the reading and discussion of papers, and executive business.

Dr. J. E. Emerson, of Detroit, reported for the committee on Eligible Fellows, of which he is chairman. The practical results of the workings of this committee is seen in the list of Fellows elected, most of whom were investigated and invited by the committee. The committee emphasizes in their report, the necessity of every Fellow considering himself a coadjutor of this committee.

The Committee on the preparation of a catalogue of Fellows, submitted two forms for arranging the names and the facts to be presented, asking directions from the Academy before additional work should be done.

The Committee on the publication of transactions suggested the issuing of an occasional Bulletin containing such papers, reports or information as the Academy would from time to time desire to publish.

The Committee on the comparative value of Academic degrees presented a voluminous report. This committee had addressed a circular letter to all the colleges in the land asking for certain facts and opinions. The report endeavored to tabulate the replies from over a hundred of them. The reports were referred to the Council, who subsequently made certain recommendations to the Academy, as will be seen a little later.

The only paper read on Saturday was entitled "The American Practitioner Abroad." It described the present status of an American physician who desires to practice in Great Britain, called attention to the fact that, while parliament enacted that after a date to be fixed by her Majesty's Council, certain foreign qualifications should be admitted to registration, the Council had never fixed the date and the enactment was a dead letter. The paper suggested that the Academy endeavor to secure reciprocity in the matter.

The more important papers were read at the session on Monday morning, the first by LEWIS H. STEINER, M.D., of Baltimore, Md., entitled

WILL A SHORTENING OF THE COLLEGE CURRICULUM CONDUCE TO BETTER PREPARATION FOR THE STUDY OF MEDICINE.

1. We are told that one great advantage will result from a shortened course, viz., the student can begin his professional studies at an earlier age and so assume the responsibilities of practice while yet young. But is it not a well known fact that youth is frequently cast up against the young doctor as an unpardonable defect in his professional make-up? Experience is sought for by a prudent public. There is now no greater urgency for this rapid creation of doctors than has existed for years, although there is a demand from the medical profession and the laity that the best preparation possible should be had by the intending doctor—that he should be a man of broad, well-rounded general culture and thoroughly trained in the principles of the profession.

2. It is said that the period of study must be diminished because students enter college now at a more mature age than in former years. But President Angell, of the University of Michigan, says that the age of entrance in his institution is not increasing but diminishing. Probably Ann Arbor fairly represents in this particular the great body of American colleges. If, however, the statement be correct it would not affect the subject very materially. Indeed, the question of age has not been raised by the advocates of full academic preparation. It is one solely of preparation, and this is believed to be best secured by the training that has heretofore produced satisfactory results. The routine of work must be adapted to the average man. The brilliant scholarly mind will compass it easily and will be able to supplement it with other important additions to his preparation for subsequent professional study, while there may be some who cannot keep abreast of the lowest requirements, and who must necessarily drop out of the struggle. This unequal contest must be expected and should the mental capacity in any case be too small to compass the college curriculum, what kind of addition to the medical profession would its owner ordinarily make? The present need is not that of mere numbers. Quality and not quantity is looked for. Possibly in this country we are so impatient of slow processes that our tendency is to superficiality. The English, the German and the French are more content to work slowly. The result of this is better all-around preparation for whatever they undertake.

The plan proposed will not conduce to the favorite object of the academy. It will accomplish nothing but an increase of college graduates. The value of the "A. B." degree will become an uncertain quantity.

This conclusion must be reached—that there must be some general consensus among medical colleges as to the nature and amount of the preliminary study and that the fact whether sufficient acquaintance with it has been attained by the applicant must be determined by some examining board. Should such board be composed of the faculties of medical colleges, or of professional men who are invested by the state with authority?

CHARLES MCINTIRE, A.M., M.D., of Easton, Pa., read a paper on

AN ATTEMPT TO DETERMINE THE IDEAL PREPARATORY COURSE OF STUDIES FOR THE LEARNED PROFESSIONS.

College education should train the mind and provide an amount of general information. The pupil himself and the personality of the teachers are important factors in an educational scheme, but as they cannot be weighed they must be treated as a constant factor in a mathematical problem. The educational world in Germany

and England as well as in the United States is in a state of unrest. With us the assigned cause is that it takes too long for a man to take a complete course and to enter upon professional life.

The plan suggested in this paper was gleaned from the opinions of a large number of college presidents obtained by private correspondence. The American system of education is not a system organized by a previous plan, but we should remember that every prolonged educational training should comprise the study of the essential studies for an educated man, having but one course so that upon its completion one can either go into business or enter college, as the case might be. This would rather shorten this period, but the pupil would enter without break into college, and in one of several courses pursue his studies with a view of mental discipline and general information. His special studies, whether professional or otherwise, would be continued in the universities, and no candidate would be admitted for a university degree unless they already possessed a college degree or could pass an examination upon the college studies. The conclusion emphasized the fact that the paper was but an imperfect representation of the thoughts of others.

The third paper was on the

GENERAL EDUCATION OF THE PHYSICIAN,

by DAVID STARR JORDAN, A.M., M.D., President of the University of Indiana, Bloomington, Ind.

The A.B. degree, as generally understood, is an index of general culture. With the improvement of our educational methods the requirements for this degree have been steadily advanced. The result is that the student who has spent all his life in the schools is not through college before the age of 22, and the man who is forced for any reason to interrupt his school work may be anywhere from 25 to 30 on graduation. This fact has led to a demand for the shortening of the college course in the interests of practical life. That the college course is too long is practically the verdict of the medical colleges and of the great body of physicians themselves. The medical colleges have made the preliminary training a matter of luxury rather than of necessity by putting into the same classes the graduates of colleges and persons who come from the country district school.

The physicians of our country say the same thing, for the number of college-bred men in medicine is lower than in almost any other profession (clergymen 1 in 4, lawyers 1 in 5, physicians 1 in 12). Of all classes of students those in medicine are, as a rule, the most reckless in their mode of life, and the most careless of the laws of hygiene and of decencies in general. This is not so true now as it was a few years ago, and for

this change the rising standards of our medical school are certainly responsible.

A writer has lately maintained that a man without independent means should not study medicine. The physician can no longer be sure of earning his living in our cities, on account of the competition of free dispensaries. But skill and wisdom will always be valued and paid for.

It is said that physicians are not taking their share in the progress of science. If this be true, and if they are deficient in general culture, may not these facts be associated? May we not have here the relation of cause and effect? Is not the remedy to bring in better men? To shut out the ignorant, trifling and unambitious, the tinker and the job worker, and reserve the training of our medical schools to those who can bring to their work the instincts, the tradition and the outlook of the scholar? The general culture of the physician should have its roots in the work of the college. If we require or recognize collegiate attainments at all, the A.B. degree furnishes the only available method by which general culture might be indicated. This standard is not absolute. It means something different in one college from what it does in another. It does not mean to-day what it did ten years ago, or what it will mean ten years hence. The value of the degree is not to be determined by the percentage of required work in any study. The essential fact is the extent to which the spirit of the scholar has been inspired in the student, and this varies in every case with the difference of teacher and scholar.

Is the standard of the A.B. degree too high for professional work? No such view can be sustained by statistics. The educated physician is the man of science; the uneducated the empiric, the quack. Our medical schools seem to think otherwise, for if general training is important the schools should insist upon it. This condition of things has two causes: 1. Most of our medical schools are scantily endowed. When a medical school is well endowed it can exact the standard the good of the profession requires. 2. The medical student has shunned the college because of the tremendous waste involved in any course of study, inflexibly pre-arranged. This waste is threefold: *a.* The time spent on subjects in no wise concerned with the future study of the subject. *b.* The time spent on subjects for which the student has no aptitude. *c.* The waste of subjects taught by dull teachers, dry, dreary, or mechanical.

If our medical schools cede four years to the culture of the colleges they have the right to ask that the colleges waste no time. The college should furnish such means of study that the future student shall not go to the medical school ignorant of the use of the scalpel and the microscope. He should also know the general facts

and theory of chemistry, and the processes of chemical manipulation. The elements of botany should be in his possession; and the facts of comparative anatomy, the great laws of life of heredity, variability, and response to external stimulus which form the basis of organic evolution. He should know what is meant by scientific investigation and should know how to use it. He should be able to write and speak good English and must read French and German. If the college permits the medical student to get a fair return for every hour he spends, the requirement of a college degree at the door of the medical school will shut out no unworthy man, nor will it hold back any in the race for life.

We may fairly regard the various degrees (A. B., B. S., etc.) given by the various colleges as alike in value, and leave the adjustment of their relation to the colleges themselves. Against spurious degrees the Academy of Medicine must be on its guard. *Scholars* can be made neither by driving nor by coaxing. In any profession the inspiration and example of educated men is the best surety that the generation which succeeds them will be likewise men of culture.

The discussion of these papers was opened by Dr. F. R. Gerrish, of Portland, Me., and continued by Drs. Herdman, of Ann Arbor, Mich.; Marcy, of Boston; Connor, of Detroit; Hill, of Iowa; Snidley, of Kentucky, and others.

The Annual Address was delivered by the retiring President, THEOPHILUS PARVIN, A.M., M.D., LL.D., of Philadelphia. Dr. Parvin's "ruling passion was strong in death," his subject being "*Miscarriages*." Unfortunately, it is a paper that does not bear abstracting, it is too concise in its entirety. The miscarriages spoken of were those of medical books, medical journals, the work of medical societies, of medical colleges and of medicine itself. Of medical books but one fifth give any recompense to the author, and at the best but a dollar a page. A still smaller proportion of medical journals pay even indirectly, and many of them likewise fail in the true work of journalism.

Medical societies, while organized for the purpose of general professional improvement, sometimes are made to promote individual interests. As to medical colleges, even in the best sometimes an unworthy man secures his doctorate. And even in medicine itself, sometimes there is a failure to cure. Methods of treatment come into the world but to die because of imperfect development. Bacteriology, perhaps, has received more attention than it deserves, and in the years to come it will not be as prominent as now. The address was concluded by an argument against vivisection as a method of medical investigation, since its results are not, without clinical confirmation, reliable, and that clinical observation is and has proved itself to be amply sufficient for the purpose.

In its executive sessions the Academy elected to Fellowship the following gentlemen:

Drs. A. B. Dunder, P. J. Surtam, N. W. Richard, L. P. Smock, A. H. Halberstadt, of Pennsylvania; G. A. Hare, J. W. Lash, G. E. Smith, F. House, C. L. Van Pelt, of Ohio; Christian Fenger, B. M. Behrens, C. M. Hansen, A. Holmboe, L. H. Mettler, of Illinois; W. W. L. Phillip, H. R. Baldwin, George Peck, of New Jersey; W. Rider, J. C. Edgar, M. N. Bemus, G. W. V. Van Voast, M. Filter, Chas. G. Cumer, of New York; S. W. Turner, J. K. Mason, of Connecticut; J. B. Brasseur, R. Peterson, V. C. Vaughan, J. N. Martin, of Michigan; A. H. Wright, of Canada; J. R. Lewis, of Iowa; W. H. Harris, of Kentucky; A. C. Rogers, J. H. Darcy, of Minnesota; Willard Springer, of Delaware; Charles Denison, of Colorado; W. R. Cluness, J. R. Smith, of California; J. F. Keeney, of District of Columbia; J. T. Green, of Arizona; and D. A. Sargent, of Massachusetts.

There were three amendments to the Constitution proposed, two of which were postponed for a year; the other, permitting the election to office of Fellows not present, was adopted.

Two years ago an amendment was adopted permitting the Council to accept other evidence of a preliminary medical education than the degree of A.B. This year, at the recommendation of Council, the Academy adopted the suggestion of the Committee, defining the nature of the evidence. Applications upon the equivalent clause must show that they have had a period of residence at some college of arts or sciences. If they are graduates, then the degree possessed must be, in the opinion of the Faculty, fairly equivalent to the A.B. degree. If the applicant has not graduated, then there must be a certificate from the Faculty of the college as to the standing of the applicant while in college, and the time of residence.

Steps were also taken for the adoption of a minimum standard for the degree of A.B.

The officers for the ensuing year are:

President—Phineas S. Conner, of Cincinnati, O.
Vice-Presidents—R. Lowry Sibbet, of Carlisle, Pa.; George J. Fisher, of Sing Sing, N. Y.; Henry M. Lyman, of Chicago, Ill.; Louis S. McMurry, of Louisville, Ky.

Secretary—Charles McIntire, Easton, Pa.

Assistant Secretary—E. M. Green, Easton, Pa.
Treasurer—J. Cheston Morris, Philadelphia.

After a satisfactory disposition had been made of the weightier matters, the Fellows in a lighter vein indulged in reminiscences of former spreads, and enjoyed the good things placed before them in the spacious banquet hall of the Arlington.

The time and place of the next meeting will be determined by the Council.

DOMESTIC CORRESPONDENCE.

Observations on "Koch's Lymph."

156 Washington ave., cor. Camp st.
NEW ORLEANS, LA., April 28, 1891.

His Excellency BENJAMIN HARRISON, President United States of America, Washington, D. C.

Sir:—I have the honor to acknowledge the following:

"Executive Mansion, WASHINGTON, D. C.,
January 19, 1891.

Professor JOSEPH JONES, Charity Hospital, New Orleans, La.

My Dear Sir:—At the President's direction I beg to send you by express, to day, one vial of Koch's lymph for such use as you may deem wise to make of it.

It was forwarded to the President by the American Minister in Germany. Very truly yours,

E. W. HALFORD, Private Secretary."

I beg leave respectfully to submit to your Excellency the following brief report on this vial of Koch's lymph.

The small vial of Koch's lymph containing about five grams (about seventy-six drops) of a dark brownish red liquid, accompanied by directions for its use, signed by Dr. A. Libbertz, of Berlin, Germany, was delivered to me in person, at my office, 36 University Place, by the express agent.

Holding that your Excellency designed this humane bequest, not for private ends, but for the benefit of suffering humanity, and the promotion of scientific inquiry, I placed a portion of "Koch's lymph" contained in the small vial, at the disposal of the medical and surgical staff of the Charity Hospital, of Louisiana, as will be seen from the following correspondence:

[Official business.] 36 University Place,

NEW ORLEANS, LA., Jan. 22, 1891.

Professor A. B. MILES, M.D., President Surgeon Charity Hospital, New Orleans, La.

My Dear Doctor:—On the 22nd inst. I received by express a small vial of "Koch's lymph," together with the enclosed communication from the private secretary of his Excellency President Harrison. . . .

I respectfully tender to the Surgeon in Charge of the Charity Hospital, and through him to the medical and surgical staff, a portion of the "lymph," for the treatment of the patients in the wards of the Charity Hospital, provided that I be furnished with accurate reports of each and every case thus treated. Respectfully your obedient servant,

JOSEPH JONES, M.D.,

Visiting Physician Charity Hospital.

Charity Hospital, State of Louisiana,

NEW ORLEANS, Jan. 26, 1891.

Prof. JOSEPH JONES, M.D., Visiting Physician Charity Hospital.

My Dear Doctor:—I beg to acknowledge receipt of your favor of the 22nd inst., tendering to the Surgeon in Charge of the Charity Hospital, and through him to the medical and surgical staff, a portion of the lymph which you have received from President Harrison.

Accept my thanks for your courtesy in this matter.

I will inform the members of the medical and surgical staff of your kind offer, and refer to you those who desire to experiment with the lymph in their ward service. Yours very truly,

A. B. MILES,

House Surgeon.

We extract the following from the official proceedings of the Board of Administrators of the Charity Hospital, April, 1891:

Dr. Miles reported relative to "Koch's lymph," in which he said the world was taking interest.

Dr. Joseph Jones had received a vial and tendered it to the hospital. He had placed a notice

on the bulletin board, inviting others to use it in safe bounds, if they thought proper. No one had applied to use it. For himself he did not care to use it yet, as he did not deem the lymph or its substance sufficiently understood. It may yet be used in the hospital, but it would be best to await further results from it.

Assisted by my Chiefs of Clinics Dr. Stanhope Jones and Dr. J. M. Elliott, I examined the cases in the wards under my care in the Charity Hospital daily, up to the middle of March, with a view to the use of "Koch's lymph" in the diagnosis and treatment of phthisis pulmonalis and other forms of tubercular disease.

That this agent or drug was not used in the treatment of diseases under my care in the wards of the Charity Hospital, of New Orleans, was due to the following causes:

a. No case presented itself which I deemed suited to the application of Koch's treatment without danger to the welfare of the patient.

b. No case presented itself of which the diagnosis was so obscure as to require the institution of a doubtful experiment.

c. Without exception the patients under my treatment and care in the wards of the Charity Hospital declined to submit to this mode of treatment.

d. The extensive prevalence of influenza, in a severe and often fatal form, and which attacked with especial violence those suffering with phthisis pulmonalis, rendered the injection of an irritating agent into the living human body hazardous.

In accordance with what I conceived to be the humane and charitable intention of your Excellency, I have held the small vial of "Koch's lymph" sacred to scientific and charitable investigations.

I have received a number of applications from physicians and private individuals for the use of this "Koch's lymph" in private practice and in institutions other than the Charity Hospital of Louisiana, and I have uniformly refused such applications. Such applications appear to have been based upon a misapprehension of the intention of your Excellency, and upon ignorance of the therapeutic value and power of a quantity of liquid too small to supply more than one drop and a half to each one of the fifty-two wards of the Charity Hospital, with a daily average of 550 and an annual average of about 7,000 cases of all diseases.

OUTLINE OF RESULTS OF CHEMICAL AND MICROSCOPICAL EXAMINATION OF THE CONTENTS OF VIAL OF "KOCH'S LYMPH."

The objectives employed in the following observations ranged from one-fifth to one-fiftieth of an inch. Due precautions were taken to secure such results as were possible in the chem-

ical and microscopical manipulation of the small amount of material.

PROPERTIES OF "KOCH'S LYMPH."

1. Reddish brown liquid, with oily movement and consistency of thin glycerine.
2. Clear, with a few minute flocculi.
3. Musty odor like that of stale beef extract.
4. When burned in flame of alcohol lamp emits an odor like burning beef extract.
5. Reaction strongly alkaline.
6. When a drop of the undiluted liquid was placed in the eye of a living animal it appeared to cause a disagreeable sensation, attended with closing of the lids temporarily, but it induced no permanent irritation or inflammation.

A repetition of this experiment caused no perceptible injury to the eye or animal.

7. No appreciable effects were induced by the "lymph" when administered internally by the mouth to living animals.

The fluid in its innocuous effects, when applied to living mucous membrane, differed from the poisonous alkaloids, and from hydrocyanic acid and the cyanogen compounds.

8. Mingles rapidly and freely in all proportions with distilled water.

9. When injected with varying degrees of dilution with distilled water (50 per cent., 25 per cent., 10 per cent., 1 per cent. and 0.1 per cent.) into the subcutaneous tissues of living animals, cats, rabbits, and guinea-pigs, only slight local irritation, and no sloughing, was induced at the points of injection. The injections were followed by fever of greater or less intensity and duration. The animals appeared to regain their normal conditions in varying periods of four to seven days, but were reserved for future observations. The liquid appeared to be far inferior in its immediate effects, when injected subcutaneously, to prussic acid, strychnine, and serpent poison. Neither did it manifest effects identical with septic poison.

10. Uncoagulated by heat.
11. Uncoagulated by nitric acid.
12. Uncoagulated by heat and nitric acid.
13. Chemically pure absolute alcohol threw down from the "lymph" a flocculent whitish deposit.
14. Solution of nitrate of silver threw down a heavy white deposit, showing the presence of chlorides in considerable amount.
15. Soluble baryta salts gave slight precipitates.

16. Stannous salts gave no evidence of the presence of the salts of gold.

17. Microscopical examination of the undiluted "Koch's lymph," with objectives ranging from one-fifth to one-fiftieth of an inch, revealed the presence of minute ovoid and rod-shaped bodies, resembling the spores and bacilli of the bacillus tuberculosis, as originally described by the eminent

microscopist, Professor Robert Koch. These microorganisms, in their size, structure, and behavior with staining agents, corresponded with the bacillus tuberculosis.

18. When the "lymph" was diluted with boiled distilled water, and preserved in chemically clean test tubes, the mouths of which were carefully and completely guarded by antiseptic cotton wool, the fluid became turbid. Microscopical examination revealed the fact that the turbidity was due to the multiplication of microorganisms presenting physical and chemical properties similar to those of bacillus tuberculosis.

19. The addition of a drop of the "lymph" to Pasteur's sterilized liquid was followed by the development of the spores and slender rod-shaped organisms resembling the bacillus tuberculosis.

20. The spores and bacilli of "Koch's lymph" were cultivated, with the necessary precautions to exclude all external germs from the atmosphere and external objects, upon various substances or media, as serum, blood, boiled Irish potato, boiled and coagulated white of egg, and boiled aseptic crystallized sugar.

21. The cultivations in fresh blood were strongly alkaline, those of the Irish potato, white of egg and sugar were acid.

22. When a small quantity of the "lymph" was added to a carefully sterilized solution of crystallizable sugar, the clear solution became turbid from the development of bacilli, and emitted a distinct sweetish acid odor, similar to that which I have often observed to be exhaled by patients suffering from phthisis pulmonalis in the advanced stages.

CONCLUSIONS.

a. The active principles of "Koch's lymph" appear to reside in a colloid nitrogenized compound coagulable by absolute alcohol, and in living germs, microorganisms, spores and bacilli, similar to those of the bacillus tuberculosis, and capable of multiplying within and without the living organism.

b. The potent effects of "Koch's lymph" when introduced into the blood of healthy and diseased human beings may be referred in part, at least, to the rapid multiplication and action of microorganisms similar to, if not identical with, the bacillus tuberculosis.

c. The results of the chemical and microscopical examination of the contents of this vial of "Koch's lymph" have led me to exclude this liquid from the list of remedial agents.

I beg to be permitted to say that in the effort to discharge what appeared to be my duty I have endeavored to serve the art, and not the trade of medicine, believing that honorable, legitimate medicine has no secrets to conceal, and holds no remedy which is not the common heritage of the

glorious brotherhood of the noble republic of science.

With great respect, and with many thanks for the generous consideration of your Excellency, I have the honor to remain your obedient servant,
JOSEPH JONES, M.D.

Letter from Dr. W. H. Daly, Pittsburgh, Pa.

To the Editor:—Replying to a letter on page 647. May 2, 1891, of THE JOURNAL of the Association, permit me to say, that at the last meeting of the Association in Nashville, I was invited to open the discussion on the medical treatment of diphtheria.

The time limit is *ten* minutes; I occupied but *six*, as can be verified by reading my remarks in THE JOURNAL of October 11, 1890. Now it is scarcely possible for one to be exhaustive on that subject, in so short a time. Much must be omitted, and I omitted much. Yet there was probably not a person who did me the honor to listen to me at the meeting, nor one who read my remarks in THE JOURNAL of the Association, with the possible exception of Dr. Kornig, who did not fully know and understand that I had already in the paper to which I referred, not only again drawn the attention of the profession to the value of the calomel treatment of diphtheria under the title of "the simplest and most efficient treatment of diphtheria," which I read before the congress of the American Laryngological Association in Philadelphia in 1886. A reprint of that article, I beg herewith to hand you, that you may see the following quotations are unmistakably correct.

You will see that I therein stated the plan was *not new* and in verification I quoted a case of the child of the celebrated author, Divine and Wit, Rev. Sydney Smith, who was treated by Dr. Hamilton in 1797 in Edinburg, Scotland, by administering 2 grains of calomel every hour—the child recovering.

You will see that I further gave my deceased friend, Dr. M. C. Reiter of Pittsburgh, full credit, which is well known not only to the estimable family of Dr. Reiter, but to the entire profession (unless possibly to the writer of that letter in the last issue of THE JOURNAL). I now quote from my remarks in that paper.

"Now, briefly, as to the credit for the practice of the calomel treatment of diphtheria in modern medicine. To Dr. William C. Reiter, of Pittsburgh, a gentleman who was learned in other sciences as well as in medicine, this credit is due. He was the apostle of this plan of treatment of diphtheria, and he for many years persistently practiced the treatment, and promulgated the doctrine to his brethren, many of whom were at first unbelievers; he was an earnest and honest observer, fearless in the practice and assertion of what he deemed right. He had large experience and ripe judgment, and, as he stood for many years almost alone in the advocacy of the

plan, he deserves still more our respectful praise and free acknowledgment.

"In medical works the various mercurial plans of treatment are mentioned, of late years, without, so far as I have observed, according to Dr. Reiter, the credit of having advocated and practiced the method of treating diphtheria by the exhibition of calomel. I regard all the other mercurial preparations as mere excuses or ineligible substitutes for this best of all mercurials in diphtheria—viz., calomel. To any one caring to see the brochure of Dr. Reiter, which is little known of, and is so peculiar in its style as to entitle it to be considered an oddity in medical literature, I will say that it was published by J. B. Lippincott & Co., in 1878, and is entitled "A Monograph on the Treatment of Diphtheria based upon a New Etiology and Pathology," by William C. Reiter, A. M., M.D."

The widest publicity was given to that paper, through the kind consideration of the medical press, and it was reprinted in extenso in several American and European journals, and in some of the latter in an abbreviated form. There were also 3,000 reprints, sent to members of the profession, especially to my fellow members of the Allegheny Co. Medical Society, of which the writer of that letter was then a member. Consequently, my disavowal of originality in the matter, as well as my just encomiums upon my deceased friend were *well* published, and *well* known, and I cannot understand how Dr. Kornig, whose name is advertised in the columns of a medical journal as a co-editor, could have failed to have read the article somewhere.

The readers of THE JOURNAL of the Association have probably all heard of the man "who on first hearing the story of the Crucifixion, hit the first Jew on the nose that he happened to meet thereafter, and on being remonstrated with, in that the event had occurred nearly 2000 years ago, justified himself on the ground that he had just heard of it, and was determined to wreak retribution."

The readers of that letter can scarcely have failed to have also read *between the lines*, and discovered a lurking animus. Altogether it presents another case of a man who has sat down with no chair behind him. Very respectfully,

W. H. DALY.

135 5th Ave, Pittsburgh, Pa.

MISCELLANY.

OHIO STATE MEDICAL SOCIETY.—Forty-sixth Annual Meeting at Sandusky, Ohio, June 17, 18, and 19, 1891.

Officers.—President, W. J. Conklin, Dayton. Vice-Presidents: D. N. Kinsman, Columbus; B. L. Millikin, Cleveland; D. J. Snyder, Scioto; Orpheus Everts, College Hill. Secretary, G. A. Collamore, Toledo. Assistant Secretary, J. A. Spence, New Philadelphia. Treasurer and Librarian, T. W. Jones, Columbus.

Committee of Arrangements.—S. S. Thorn, A. J. Gayne, H. A. Tobey, Wm. Caldwell, F. D. Bain.

First Session—Wednesday, June 17.—1. Call to order.

2. Report of Committee of Arrangements.

3. Business which requires early consideration.

4. Annual Reports of Treasurer, Librarian and Secretary.

5. Reports of Standing Committees: Committee on Admissions and Medical Societies, Committee on Finance, Committee on Publication, Committee on Legislation, Committee on Ethics.

6. Reports of Special Committees: Committee on "Act providing for the Protection of Physicians, etc." P. S. Conner, Chairman. Committee on Organization of County Societies and their Relation to the State Medical Society. T. A. Reamy, Chairman.

7. Reports from Delegates to the American Medical Association and other Societies.

8. Appointment of Committee on Nominations.

9. Papers: "The Surgical Treatment of Chronic Catarrhal Appendicitis," R. Harvey Reed, Mansfield. "Notes on the Treatment of Syphilis," W. T. Corlett, Cleveland. "A Plea for a More Extended Supervision of the Parturient Woman," D. R. Silver, Sidney. "Hernia," Dudley P. Allen, Cleveland.

Evening Session.—1. Papers: "Carcinoma, a form of Perverted Nutrition," H. J. Herrick, Cleveland. "A Rare Case of Pelvic Dropsy; Operation; Cure," J. F. Baldwin, Columbus. "Spinal Supports," S. L. McCurdy, Dennison. "Compound Ganglia; Treatment by Operation," C. S. Hamilton, Columbus. "Three Cases Radical Cure of Hernia by the Use of the Buried Antiseptic Animal Suture," F. C. Larimore, Mt. Vernon.

Tuesday, June 18.—Morning Session.—1. Reports of Committees.

2. Papers: "A. C. E. Mixture," J. C. Reeve, Dayton. "Anæsthetics: the Dangers in the Use of Chloroform as compared with Sulphuric Ether," E. H. Hyatt, Delaware. "Tuberculin in the Treatment of Tuberculosis," J. T. Whittaker, Cincinnati. "Influenza," N. C. Kinsman, Columbus. "Convergent Squint and its Cure," C. W. Tangeman, Cincinnati. "Some Facts every Practitioner ought to know about Squint," A. R. Baker, Cleveland. "The Treatment of Retention from Hypertrophy of Prostate," N. P. Dandridge, Cincinnati. "Fracture of Dorsal Vertebrae," A. W. Ridenour, Massillon.

Afternoon Session.—1. Reports of Committees.

2. Election of Officers.

3. Selection of the Place for the next Meeting.

4. Papers: "Report of Cases, with Comments," T. A. Reamy, Cincinnati. "Removal of Uterine Appendages; Supplemental Report," R. B. Hall, Cincinnati. "Operative Treatment of Uterine Cancer," D. Tod Gilliam, Columbus. "High Amputation of Cervix," B. F. Hart, Marietta. "Cases of Extra-Uterine Gestation," W. D. Hamilton and C. S. Hamilton, Columbus. "The Value of Draining the Pelvis, in Case of Bleeding after Operation," M. Stamm, Fremont.

Evening Session.—President's Address: "A Page of Medical History; Moliere and the Doctors," W. J. Conklin, Dayton.

Friday, June 19.—Morning Session.—1. Reports of Committees.

2. Papers: "Modern Methods of Treatment for Nose and Throat Diseases accessible to the General Practitioner," Jas. E. Nichols, N. Y. City. "Tonsillotomy and After-Treatment," T. V. Fitzpatrick, Cincinnati. "Intubation," Geo. Goodhue, Dayton. "Papilloma of Larynx; Case," A. B. Thrasher, Cincinnati. "Exploratory Incisions of Knee Joints," B. Merrill Ricketts, Cincinnati. "Gonorrhoea in Women," C. N. Smith, Toledo. "Home versus Hospital Treatment of the Insane," A. B. Richardson, Cincinnati.

Afternoon Session.—1. Reports of Committees.

2. Papers: "Hyperemesis Gravidarum," W. A. Dickey, Tiffin. "Tests for Albumen," W. B. Davis, Cincinnati. "The Limitations of Dermatology," Edward Preble, Cleveland. "Spinal Concussion," G. W. Crile, Cleveland. "Salpingitis; with a Report of two Cases," A. B. Walker, Canton. Volunteer Papers.

3. Oral Communications.

4. New Business.

5. Unfinished and Miscellaneous Business.

As the program contains a large number of papers, the attention of readers is called to Section V, of By-Laws: "Not to exceed thirty minutes shall be allowed for the reading of any paper."

The Sessions of the Society will be held at the Hall corner Washington Row and Jackson Street; first Session at 2 P. M., Wednesday, June 17.

Hotels.—West House; Sloane House, \$2.00 and upward per day.

DR. SAMUEL O. L. POTTER, Professor of Medicine in the Cooper Medical College of San Francisco, and a graduate of Jefferson Medical College of Philadelphia (with first prize, '82), recently passed the required examination and was admitted on April 30 last, a Member of the Royal College of Physicians of London, forming one of a class of nine candidates, all of which were M.D.'s of British Universities, viz.: three of Cambridge, one of Oxford, one of Edinburgh, two of London, one of Aberdeen.

Those who understand the peculiar rank of British qualifications will recognize the M.R.C.P. of London as the "hall-mark" of the British medical profession, and that it is a coveted one may be seen from the fact that all the candidates therefor were previous M.D.'s or M.B.'s of universities—asking this as an additional honor. The qualification of this college given at the ordinary final examination of students is the license, "L.R.C.P." London, and does not admit, as does the membership, to the college itself.

The only other Americans holding this qualification are Prof. Osler, of Baltimore, and Dr. Robinson, of San Francisco. It is also held by two English practitioners in California, and one in Washington, one in Canada, and one in British Columbia.

We understand that Dr. Potter left his bed in convalescence from broncho-pneumonia to undergo the examinations of the week ending April 30, and that he has since had a relapse and is dangerously ill.

OFFICERS OF KANSAS STATE MEDICAL SOCIETY for ensuing year: President—J. E. Oldham, M.D., Wichita, Kan.; First Vice President—A. H. Cordier, M.D., McPherson, Kan.; Second Vice President—J. T. Axtell, M.D., Newton, Kan.; Treasurer—L. A. Buck, M.D., Peabody, Kan.; Secretary—W. S. Lindsay, M.D., Topeka, Kan. Next place of meeting, Ft. Scott, May, 1892.

THE SOUNDS OF COLORS.—A beam of sunlight is made to pass through a prism so as to produce the solar spectrum or rainbow. A disc, having slits or openings in it, is made to revolve, and the colored light of the rainbow is made to break through it and fall on silk, wool, or other material contained in a glass vessel. As the colored light falls upon it, sounds will be given by the different parts of the spectrum, and there will be silence in other parts. If the vessel contains red worsted, and the green light flashes upon it, loud sounds will be given. Only feeble sounds will be heard when the red and blue parts of the rainbow fall upon the vessel.—*Times and Register*.

IMPROVEMENT IN MICROSCOPIC LENSES.—It is stated that an immense improvement has recently been effected in the manufacture of glass for optical instruments, by means of the addition to the ordinary materials of phosphorus and chlorine, which in some, as yet unexplained, way cause the glass to be very much more transparent, and enable it to receive a much higher

degree of polish than any optical glass hitherto manufactured. Thus microscopes can be made which will render objects of the diameter of only the one-eight millionth of a millimetre visible, whereas with the best instruments now in use the diameter of the smallest object that can be seen is one-sixteenth thousandth of a millimetre.—*Lancet*.

THE AMERICAN MEDICAL ASSOCIATION.—The meeting of the Association which has just closed at Washington, was in many ways a success. With such a man as Dr. Briggs in the chair, and master minds like Shurly and Mathews, to give the principal addresses, the general sessions could not but be interesting. Those who have read the thoughtful addresses already published must feel proud of the men who can so grace our guild by word and deed.

The reports of the sections are not as yet ready, but it is safe to anticipate their reception, and say that each year there is a growing demand for more and better work in each section. Sometimes, indeed, it seems that the main drift of the Association is political, that the main chance is with the committee on nominations and the chief prizes are the leading offices; just then some grand work will be announced, some reliable conclusion given, or some valuable research reported and the scientific worth of the Association will again be in the ascendency.

Thus, as in all progress, there is an ebb and flow and we are satisfied if only the tides does not run too low, as it sometimes threatens to do. We confidently believe, however, in the great field of usefulness which the American Medical Association is to occupy. Some changes must be made for the greater economy of time and the proper selection of material; some advantages may be gained by the formation of local branches, and some new enthusiasm aroused by holding out inducements for scientific research and original investigation.

The American profession is pledged to the support of the American Medical Association and there must be its hindrance to its progress and no prostitution of no purposes.—Editorial in *The St. Louis Clinique*.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from May 10, 1891, to May 22, 1891.

Capt. Marshall W. Woods, Asst. Surgeon U. S. A., is hereby granted leave of absence for one month, to commence on or about the 23d inst. Par. 1, S. O. 104, Div. Atlantic, May 20, 1891.

Capt. George McCreery, Asst. Surgeon, is relieved from duty at Ft. Clarke, Tex., and will report in person to the commanding officer, Ft. McIntosh, Tex., for duty at that post. By direction of the secretary of War. Par. 4, S. O. 114, A. G. O., May 19, 1891.

Capt. William B. Banister, Asst. Surgeon, is assigned to duty as medical officer with Troop B, Sixth Cavalry, while en route from Ft. Myer, Va., to Ft. Washokie, Wyo. On arrival of the troop at its destination, Capt. Banister will return to his station at Washington Bks. Par. 3, S. O. 104, Div. Atlantic, May 20, 1891.

Capt. John A. Skinner, Asst. Surgeon U. S. A., Ft. Davis, Tex., will proceed at once to Ft. Clarke, Tex., and report to the commanding officer for temporary duty. Par. 1, S. O. 44, Dept. of Texas, May 13, 1891.

By direction of the Secretary of War, the following assignments of recently appointed medical officers are ordered: First Lieut. William F. Lippitt, Jr., Asst. Surgeon, will report in person to the commanding officer, Ft. McPherson, Ga. First Lieut. Benjamin Brooke, Asst. Surgeon, will report in person to the commanding officer, Ft. Riley, Kan. First Lieut. Meritt W. Ireland, Asst. Surgeon, will proceed from Columbia City, Ind., to Jefferson Bks., Mo., and report in person for duty to the commanding officer of that post. First Lieut. George M. Wells, Asst. Surgeon, will proceed from Ellij, Ind., to Columbus, O., and report in person for duty to the commanding officer of that post. Par. 7, S. O. 115, A. G. O., May 20, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending May 27, 1891.

Surgeon Geo. A. Bright, detached from U. S. S. "Omaha," and granted three months' leave of absence.

P. A. Surgeon V. C. B. Means, detached from U. S. S. "Omaha" and granted three months' leave of absence.

Asst. Surgeon Jas. F. Keeney, ordered for examination preliminary to promotion to P. A. Surgeon.

THE CONSIDERATION AND CURE OF CHRONIC TUBERCULAR CONSUMPTION OF THE LUNGS.

*Read in the Section of Practice of Medicine and Physiology, at the
Forty-second Annual Meeting of the American Medical Association,
held at Washington, D. C., May, 1891.*

BY ASA F. PATTEE, A.M., M.D.,
OF BOSTON, MASS.

In the preparation of this paper I have endeavored to be as concise as possible consistent with clearness; I have employed the terms phthisis, tuberculosis and pulmonary consumption as expressing the same pathological condition.

The progressive tendency of the tubercle of phthisis is of a fibrous nature, or a leaning toward healing or health; becoming through this means a self-limiting condition. The direct reverse of the tubercle of cancerous and other inflammatory ulceration.

I have for many years maintained by theory, and shown by actual results, that pulmonary tuberculosis may be cured, even after extensive degeneration of lung tissue has taken place; provided the constitution has not become vitiated by disease or other causes, or its recuperative powers destroyed by old age.

We now find this assertion copiously substantiated by eminent authority. Given suitable handling, in all that the term implies, and the extent of the depredation will take care of itself; it will make little difference whether prognosis has limited the life of the patient to a certain number of weeks or months.

It is the cowardly attitude of settling down to palliative measures that has wrought the mischief in the past. Such means exclude all recuperative agents, and serve to deprive every organ of its normal activity in the performance of its functions, as a result favoring the destruction already going on.

This idea that a person must be doomed to die of phthisis because one of his parents were its victims seems now about to be thrown into the rubbish of the past, and the sooner this absurdity can be removed from the mind of the public the better.

GENERAL TREATMENT.

My thesis written in 1857 was entitled, *Pure Air, Pure Water, Cleanliness and Exercise*. Their importance in the prophylaxis and cure of disease.

From the time I commenced practice these agents have been my best allies. In my surgery, air, water and cleanliness have been my antiseptics, pure water doing for me what corrosive sublimate, iodoform, etc., have accomplished in the hands of others.

In 1862, I first read Chamber's Lectures on the Renewal of Life, and so impressed was I with the truth of his reasoning that I have kept that object in view in the treatment of disease in every form ever since. The number of cases of chronic pulmonary tuberculosis that have come into my hands for treatment are, according to my reckoning, about 3,000, exclusive of those I had in the United States Army. Every case shows me yet more plainly the folly of attempting to adopt a routine which shall be applicable to all tuberculous patients. The treatment of every patient must be a problem unto itself.

By no means is it essential for the same unfavorable elements to combine in order to bring about certain results. The susceptibility of the individual to certain conditions must be considered. We must meet every condition, physically, mentally and morally, and in this way regard his case as entirely distinct from any other.

While the various theories as to predisposing causes, hereditary tendencies, and the means of combating them have not embraced all the elements of success, still they have given us all the light we have had upon this dark subject, and so far as hygienic influences have been recognized they are deserving of our highest consideration.

Until the bacillus made its shadow upon the screen of our observations whose office it seems to me should be regarded as that of a very lively interrogation point, rather than as a period to all future questionings, the trend of the past few years had been towards recognizing in Nature a powerful factor in the prevention and cure of consumption.

Let us not get bacilli mad! Cannot we have a case of pulmonary tuberculosis on our hands and not yet be able to find these little fellows;

the very recent knowledge of whose existence seems to have wrought a condition in our brains as disastrous as their presence is credited to produce in the lungs of our patients?

Let us not forget our modest days of small things, before bacilli were known, and thus carefully avoid the danger which now seems to be threatening of ignoring all other means of diagnosis in our frantic search for the revelations of the microscope.

Nor will we permit this to let us slight the premonitory warnings of the approach of this disease, and thus encourage the baneful tendency to dismiss, with some simple opiate, a slight cough, protracted cold, irritable throat, etc., because as yet the expectorations have failed to yield the little wriggler whose presence only shall determine the tuberculous condition.

If tuberculosis must owe its existence to this alone, then I shall maintain, at the expense of paradox, that he who would cure chronic pulmonary tuberculosis must begin the cure before he finds the disease in his patients.

Build up the general health of the consumptive so that his chemico-vitalizing function will be sufficient to destroy the bacilli. In fact, put every patient into such a degree of health that he shall be his own bacilli-killer.

Bacilli cannot exist in perfectly healthy lung tissue. It must become diseased before it can offer sufficient inducement for him to live and propagate in it, and upon its resumption of health the tenant vanishes.

HYGIENIC INFLUENCES.

A perfect familiarity with the daily life of our patient must be our first consideration. Our surroundings make us what we are, physically as well as morally and socially. Man is like the chameleon, every part of his nature partakes and is made up of his surroundings. "Show me your friends and I will tell you what you are." This is as true of the physical as of the moral man.

If our treatment could begin with the birth of the patient, in 99 per cent. we should have no tuberculosis to treat, no matter about the family history.

Fear is a powerful provocative to physical degeneration. Take the condition of the poor. It is not generally their immediate wants which cause the catastrophe. People who are habitually poor are not necessarily feeble, but those who have lost their wealth are the sufferers. Fear as to the immediate future for themselves or others; with this instinctive nervous shock the body shrinks, all the organic functions are disturbed. Especially is this true of the respiratory functions. Fear of any sort has a depressing effect upon the respiratory centre. This is as true of animals as of men. Anxiety is but a species of fear.

It is futile for us to shut our eyes to the reflex action which the mind throws upon the physiological powers. We see proofs of it every instant, yet dispute it, and call it unscientific. What are we striving to accomplish in our treatment of disease? Is it not our aim to coax, by all manner of means known to us, this vital principle called Life to tarry yet a little longer in its diseased encasement? Then give its presence a just recognition by attributing to it a capability both creative and destructive, a reality though intangible.

EXERCISE.

The various mechanical arrangements now in vogue for indoor exercise are generally to be commended. The patient must be imbued with the determination to get well. He must be made to understand that much depends upon himself. That he must exercise as well as eat. The exercise must be accumulative, doing a little more every day, and the nourishment must also be accumulative. The amount of exercise he can bear will depend upon the amount of strength-giving food he can assimilate, and vice versa.

RECREATION.

The recreations should be of a nature that will inspire an interest on the part of the invalid in their accomplishment. There should be an importance attached to them requiring some thought. The unemployed mind is a powerful depressant to the nervous forces. Let the daily walks and rides have some purpose, if nothing more than the performance of the domestic errands of the family. If he loves art and music his tastes should be gratified. There should be a moderate indulgence in out-of-door sports, as bicycling, ball, surf bathing when allowable, horseback riding and skating. Our lady patients have their gymnastics, tricycle, horse-back riding and skating, and of great importance, their vocal gymnastics. This will expand the lungs and strengthen the pectoral and respiratory muscles. Being a pleasant recreation, and at the same time a most excellent means of bathing the air-cells with oxygen and teaching the vocal organs the proper performance of their functions. After a few weeks of judicious practice the dimensions of the chest will be found to have increased from four to five inches.

Practicing at the piano, needle-work or any employment which requires close application and necessitates contraction of the chest walls in its performance, should be forbidden.

DAILY CARE OF THE PATIENT.

Our phthisical invalid should have the constant attention of a well-trained nurse. His room must be sunny, with pleasant prospect from the windows. No stuffy furniture, no carpets, no fancy articles hanging or standing about, ready

upon their slightest agitation to disseminate the accumulated dust of stagnation and disease. If possible, the walls of the room should be painted. They can then be wiped off occasionally with some disinfectant, as borax water or Platt's chlorides. Place pine, spruce or fir boughs about the room and under the bed the patient occupies; this will impart to the atmosphere an agreeable odor, and has undoubtedly the effect of calming laryngo-bronchial irritation and diminishing the frequency of the cough. I am convinced of the benefit of breathing this air. It is also well to spray some agreeable antiseptic about the room, as essence of cinnamon, clove, gaultheria, eucalyptus, etc.

The bedstead should be of metal, having a fine wire spring, hair mattress and fine wool blankets; no draperies.

If possible, let the artificial lighting be of electricity, but if gas must be used, see that the burner is a proper one to consume all the gas as it is forced through. Avoid lighting or heating by kerosene oil; a kerosene lamp or heater consumes more oxygen than the patient does himself.

The temperature of the room should be equal, ranging from 68° to 70°, and in the damp and rainy days of summer it must be made dry by a grate fire or some other form of heating.

The underclothing of the patient should be of wool the year round, and changed every day. There is no necessity of encasing him in very thick, unyielding flannel; it seems rather to produce a weakening effect by preventing the free escape of the exhalations of the body; those which are loosely worn and of light weight and soft texture serve a better purpose.

The nurse must be able to manipulate the patient's body, rubbing, lightly pounding or patting and beating with a whisk broom. In beating the surface in this manner it has a direct stimulating effect upon the peripheral nerve-endings, and produces a vitalizing influence that cannot be obtained in any other way; for in the broom we have anywhere from 1,000 to 2,000 twigs of different sizes, and this beating of course produces as many different vibrations upon the nerves and nerve-centres, thereby increasing wonderfully the power of the skin in appropriating oxygen and nutrition.

The bowels should be kneaded; a most excellent process for obstinate constipation. Rubbing with flannel may at times replace the bath when the patient feels a repugnance to water. The limbs should always be rubbed towards the body. Rubbing with flannel charges the person with an amount of electricity which cannot be produced in any other way.

In women patients there must be absolute freedom from dragging skirts, tight bindings and garters. The dress must allow perfect liberty of action in chest and limbs. I do not object to

corsets if they are worn loose. A thin patient insists that they are a support to her; in the place of injury, I think they are a benefit; but they must be worn loose enough to not interfere with the movements of the diaphragm. She should wear felt shoes, neither laced nor buttoned tight around the ankles; cold feet at night invariably follow the wearing of closely-buttoned boots during the day.

FOOD.

While pure air may be prescribed without limit, and the same sanitary surroundings are equally beneficial to all, yet when we come to the question of diet, we cannot prescribe in a general way; we must be guided by the likes and idiosyncracies of our patients. We may find one to thrive on pure milk and occasionally one who can take cod-liver oil with benefit, while the digestive organs of another will be thrown into a terrible state of disorder by these agents.

The patient must have regular times for eating solid food. It must be taken at least every four hours, and drinks between times, of milk, beef tea, aromatic teas, gruels, fruit juices, etc. Milk when well borne and assimilated is nourishing, strengthening, and fattening, and we have great occasion to be glad when we find it can be taken in large quantities and digested. Unless we can get milk that is fresh from the cow, the condensed milk without sugar is preferable to old milk.

Infusions of malt, when properly made, may be taken by nearly every one. And instead of undertaking the digestion of thick malt extracts a simple infusion like the following will be much better: Malt in coarse powder, 4 ounces. Water heated to about 86° F., 12 ounces. Macerate for four hours at a temperature of about 100° F. Then gradually raise it to about 130° for half an hour; strain this infusion with strong expression and add one grain of salicylic acid. This quantity can be taken every day; it can be flavored at any time by adding a drachm of hops, chamomile flowers, or any of the aromatic herbs. This will be found far superior to any of the thick malt extracts. I do not advocate the use of cod-liver oil; as a usual thing it will derange the stomach and prevent the patient from taking a due amount of suitable food. Cod-liver oil cannot supply the place of meat, bread and butter, but meat, bread and butter can more than supply the place of cod-liver oil.

Man being omnivorous, should have variety in his food. Juices of meat, and the fat of newly made butter and sweet cream. Also vegetables cooked with some good fat meat should form a part of his diet, but in very small quantities. The expressed juice of different kinds of berries, pineapple, etc., may also be partaken of. The consensus of opinion has been that meat is better the

longer it has been kept, but I contend that the sooner meat is eaten after it is slaughtered the more health and life-giving properties it has; the same is true of milk, the sooner it is drunk after being drawn from the udder the better.

All food should be disintegrated when eaten with copious draughts of pure water or some agreeable aromatic tea. This I have always maintained, through the long-drawn misery of the dry food mania, at the expense of severe criticism from my professional brethren. The patient should consume at least three pints of water in the twenty-four hours, and more if necessary. We know that water forms three-fourths of our animal economy, that it enters in the same proportion into all animal life, hence consumptive patients must take a large amount of liquids. We also know that water has solvent powers, that it will often overcome the most obstinate constipation, that it is also a powerful medium for removing effete matter from the body, acting on the alimentary canal both mechanically and chemically by changing their atonic condition and enabling the absorption of nutritious food. The addition of one-third to one-half parts of pure water to milk has been more effectual in preventing the formation of curd than lime-water, and a mixture of equal parts of water and milk, or infusion of malt, will quench the thirst of phthisical patients, reduce the temperature, and have a quieting effect. Not infrequently this can be borne better than either separately.

Ice-cream made from rich cream and milk may be eaten sparingly when the patient is feverish and craves cold food and drinks. The peptonized milk of Reed & Carnrick is good, and adds to the variety, also their beef peptonoids. Never allow the patient to eat yeast-made bread, it must be made from cream-of-tarter baking-powder, and twice baked, (*i.e.* lightly toasted).

The food must be varied; surprises in the way of unexpected dishes are a stimulant to the appetite. Fresh beef broiled, or scraped and eaten raw, or made into little patties and nicely seasoned and sparingly broiled over the coals; or, have the lean meat, free from fat and fibrous tissue, chopped in an enterprise chopper and to each pound of meat add one-fourth pound of fat breakfast bacon. This can be carefully broiled, salted and flavored to the taste and makes a most toothsome morsel. The patient rarely tires of it. He should eat from two to three pounds of this during the twenty-four hours.

Pig meat is not the worst kind to eat by any manner of means. I have no reference to the New England hog fed on slops, wallowing in filth, shut up in a seven by nine box without fresh air from birth to the day of slaughter. I refer to the much maligned western hog, that knows not what filth is, that from its earliest predecessors has had pure air and cleanliness, and been fed on

nuts, corn and wheat. Such meat is healthy and digestible. One or two teaspoonfuls of gluten may be included in the diet, cooked or uncooked, as suits the stomach. Fish can be partaken of once a week, also oyster and clam juice.

The patient should not be made to eat alone in his room; the pleasures attendant upon eating have much to do with results. Shut off from a life of activity, the feeling will come sooner or later according to his temperament, that he is a doomed man. There is always a tendency in the person suffering from any chronic ailment to foster the idea that he is of no account in the world because of his debility.

The object of the diet should be to nourish, strengthen and fatten. When we find our patient digesting his food, picking up in flesh and getting stronger every day, we have reason to believe his recovery is not only possible, but probable.

SLEEP.

"The death of each day's life,
Sore labor's bath,
Balm of hurt minds."

Sleep is but another form of food, and is not less essential than the food we take into our stomachs.

No matter what the disease, we know its malignancy has yielded when the periods of long, sound, natural sleep advance. As a prophylaxis, sleep ranks among the most important. Only through sleep can the nerve-centres relax and recuperation begin.

During the night of healthy sleep the scavengers of the body are working noiselessly with their implements of conveyance, preparing for the morrow's labors.

Darkness is the period of perfect rest. Until the human mind discovered the means of substituting by artificial light that of the sun, mankind retired with its declining rays. Children—of whom it has been said, their life, as it develops, give a fair representation of the lines of human progress—naturally seek repose at sunset. Nature herself at this time seems to be hushing all animated life to sleep upon her bosom.

How different is man under the influences of civilization! Insomnia and neurasthenia are the terrible beasts born of his enlightenment. Lashing their victim night and day until he would willingly offer his soul in exchange for the sound healthy sleep of the barbarian!

Insomnia is to-day the most familiar foe we meet, so prolific in its capacity that without exaggeration or fancy we can ascribe to it the common beginning of a vast part of our chronic ailments. It has come to have an *individuality*, and is no longer a symptom only. One of the common causes of this is the artificial light which is found in the majority of sleeping-rooms during the night, not only of lamps and gas, but the rays of

the electric light stream through our windows. Although the eyes may be closed, we are conscious of the changes in its flickering glare. The patient becomes accustomed to it and feels that he cannot have it excluded, and so we have added another to the "necessities of civilization."

Not the sleep to be had during the day, but the repose at night must be encouraged in the patient. Discipline will do much toward capturing this sly visitor, other things being equal.

The patient must retire early, he should not exercise his brain by reading or talking after seven o'clock. In summer he should be in bed for the night by eight o'clock, and in winter by seven o'clock. In the summer he should rise in the morning between five and six o'clock, and from seven to eight o'clock in the winter. The room should be of a proper temperature, so he experiences no chill in bathing and dressing.

The night-dress of the patient should be of sufficient thickness to protect the body and allow perfect freedom of movement and position without risk of chill. The flannel undervest worn during the day should be removed at night and one of lighter weight substituted. Bathing before retiring has a tendency to induce sleep. It should be accomplished in a manner the least calculated to task the patient's strength. If the temperature is normal, a wet cloth passed over the body and wrung out in fresh water may take the place of the bath; rub the skin well afterwards.

If the feet are cold they must be made warm and kept so; the means to be employed for this purpose are very numerous. Among the best are, the wrapping each foot in flannel separately, and the hot water bag (but the old-fashioned hot soap-stone is better). These are only palliative; for the removal of this condition there is nothing equal to manipulation done after the following: Begin at the nape of the neck, placing the ends of the first and second fingers firmly on each side of the spinal column, carrying them firmly and evenly downwards its whole length; repeat this several times. After this rub well the soft hollows in the ankles each side of the heels and around the joints. The patient will soon begin to feel the blood rushing into his feet, and ere many nights he will have the satisfaction of seeing a healthy circulation established in these parts.

Beef tea, beef peptonoids or some other light form of food should be served the patient directly on his awakening in the morning.

PURE AIR.

When practicable the person should be sent into a hilly district where he can have the advantages of a high and dry atmosphere. Avoid lakes and all bodies of fresh water. Otherwise as good air can be obtained in the city as in the country.

Boston is particularly fortunate in this respect. We should be grateful for the easterly winds, though they have given our town an unfavorable notoriety. Their salty breath cool and purify the atmosphere and render it a habitable city in the summer, even in the meanest localities.

I believe the bedrooms of the populace are generally tolerably well ventilated.

A certain class of enthusiasts upon the subject of ventilation have fallen into the error of overdoing the thing, or in doing it so badly that it becomes an injury, by allowing the air to come in stratas, making a draft upon the sleeper, whose powers of resistance are diminished.

It is a good plan to have the ventilation come through the windows of an adjoining room when possible. As the sleeping person does not require so much air as when he is up and around, it is not necessary that he should be deluged in a constantly changing current.

BATHING.

The superficial application of moisture to the body which the patient receives at night is not for cleanliness. He should have a daily bath, adding to every quart of water a teaspoonful of powdered borax or tablespoonful of aqua ammonia. Also use soap having an agreeable perfume. After he has been well wiped with a rough towel he should be anointed with nice fresh lard thoroughly beaten to a creamy consistency and perfumed to suit the fancy of the patient. Instead of the lard, petroleum, coca-butter, cottonseed oil, can be used, perfumed by the addition of some agreeable essential oil. The Turkish bath, shower-bath, cold pack, all have their place, and the hot spinal rubber bag for hæmoptysis.

MEDICAL TREATMENT.

It would be impossible for me, in a paper of this nature, to enter into details of treatment for every tubercular condition, so I have grouped in the following lists the remedies I use for the various requirements of the disease, employing them singly or in combination as occasion may require.

The first thing to be considered for our consumptive is his power of digestion and assimilation. His food must nourish and strengthen.

I find in the majority of cases it is beneficial to begin treatment by giving from one to five grains of calomel at night, followed in the morning by one or two drachms of sulphate of soda. This I should do whether the tongue be clear or foul, whether there be diarrhoea or constipation. Repeat for two or three nights as indicated; at the same time he must sip one-half pint of hot water slowly at least half an hour before meals. If there is tendency to constipation after the calomel and soda have passed off, give one or more of the following remedies:

FOR CONSTIPATION.

Sodium phosphate, sodium sulphate, magnesium sulphate, oleum ricini, rhamnus frangula, rhamnus purshiana, euonymus, atro-purpurinus, juglandis cinera, sulphur. Appropriate doses after meals of one or more of these remedies, not only act as peristaltic stimulants, but they favor the process of nutrition; the patient gains in appetite and strength.

After the whole alimentary tract has been brought into the best condition possible, so that the patient has a good appetite and is digesting his food well, the following pill may be given: Zinci cyanidi, aurei cyanidi, zinci oxidi, thirty grains; extract cannabis indica, six grains; extract ignatia, three grains, glucose quantity sufficient to make thirty pills. Give one pill after the three principal meals.

Among the appetizers I have used the following infusions: Absinthium berberis, calumba, cannabis indica, benzoin odoriflrum, baldo, calisaya bark, gentian and quassia.

For the general cachectic condition of the patient's body (after the condition of assimilation has been accomplished), I have employed on different occasions the following, using them singly or in combination, as occasion seemed to demand: Aurum et sodium chloridum, aurum cyanidum, calcium chloride, calcium iodide, calcium sulphuratum, cuprum arsenicum, sodium arsenicum, hydrargyri cyanidum, hydrargyri corrosivum chloridum, hydrargyri bin iodidum, sulphur, ferrum cyanidum, zinci cyanidum, potassii sulphuretum, nitro-muriatic acid, phosphoric acid, malic acid, creosote, guaiacol, terebene.

INFUSIONS.

Rhamnus purshiana, rhamnus frangula, leptandria, hydrastis, euonymus, populus tremuloides, pyrus mallus, pyrus Americana, stillingia sylvatica, rumex crispus, phytolacca decandra, alnus rubra, benbenis aquifolium.

FOR THE DIARRHOEA.

The following infusions may be given: Blackberry root, sumach bark, pulverized coto bark, logwood. Also tincture of ipecac, and bismuth subnitrate, bismuth salicylate, acidum carbolicum, salol, zinci oxidum, cuprum arsenitis, oleum ricini, and enemas of warm water with hydrastis.

I have also used the following powder a great deal: Zinci oxidi, two grains; sodii bicarb., five grains; pulverized coto bark, one grain, mix. This makes one powder. Take this amount after every meal. Also give cooling, healing drinks, as flax-seed tea, slippery elm, etc.

The hot stomach pad is of great benefit in all stomach and bowel diseases. It removes flatulency, pain, distension, etc., and is valuable in inducing sleep at night. It is made by taking

1. Eight thicknesses of thick cotton crash, 12 x 6 inches.

2. A cotton flannel binder, 12-14 inches wide, and long enough to go around the body, with tapes sewed on the ends to secure it.

3. A duplicate of the latter made of waterproof or mackintosh.

4. The same made of flannel.

The pad must be put into boiling salt water in proportion of one ounce to a pint, then wrung out and applied to the stomach and abdomen as hot as can be borne. Tie the flannel binder, the waterproof, and lastly the outside flannel tightly. When cold it must be removed, put through the hot water again and re-applied. This can be worn two or three hours every day after meals, or if much pain is present, it must be worn constantly. It will improve digestion and promote assimilation to a wonderful degree.

DIGESTIVE FERMENTS.

We have two animal ferments, pepsin and extractum pancreatis; our selection must be governed by the nature of the indigestion. Of the vegetable ferments we have a variety; among them are juice of the carica papaya (South American paw paw); asimina triola, juice of the unripe fruit; anassa satina (pineapple), juice of the ripe fruit; infusion of ficus carica (fig), drosera rotundifolia; musa sapientum (banana), juice of ripe fruit.

For the fever of the first stage I have found selections from the following to be all that were required, used either singly or combined, according to conditions: Norwood's tincture of veratrum viride, tinctures of aconite, gelsemium, lycopus virginica, comicifuga, also antimoniæ et potassii tartras.

I find these give better results than the newer antipyretics, as acetanilid, antipyrin, etc.

Fever of the second stage: Salicylic acid, salicina, acetanilid, antipyrin, phenacetin, quinia hydra-bromate, salicylate of ammonia.

For the night sweats: Atropia sulphate, picrotoxin, malic acid, zinci oxidum, zinci cyanidum, tincture cocculus indicus, sage tea.

For the sore mouth and the follicular ulceration of the mouth and pharynx. Touch the ulcerated spots with a sulphate of copper crayon, and rinse the mouth with a solution of chlorate of potash of the strength of eight grains to the ounce of water, and one drachm of glycerine. (But a few spots should be treated at one time.) In the sore mouth where the mucous membrane looks red and shining, an infusion of rhus glabra or prinos verticillatus, or hydrastes, alnus rubra, and salix nigra may be used with glycerine, one drachm to the ounce. Rinse the mouth freely.

If the secretion of saliva is scanty, the addition of a vegetable acid to the infusion will be necessary. If profuse, add an alkali, as the bicarbonate of sodium or potassium.

For the cough: The general constitutional treatment with the mouth washes, gargles and inhalations, will be all that is necessary unless it should be so troublesome that the patient cannot sleep at night. In that case, give one-third of a grain of codeina, with one-twentieth of a grain of apomorphia hydrochlorate, at bed time. I give preference to the simple codeina to any of its salts. I find it works better.

For a loose cough: Nitrate of sanguinaria, one grain; sodii phos phus, one-half drachm, simple elixir, glycerine, of each two ounces; tincture phosphora, one drachm; mix and give from one-half to one teaspoonful every three hours, in an infusion of pine bark tea.

For asthmatic cough: Nitrate of sodium, nitro-glycerine, weak alcoholic tincture of grindelia robusta, inhalations of nitrate of potash paper.

For the intercostal neuralgia the following liniment will give great comfort and relief: Olei ricini, olei terebinthi, olei eucalypti, of each one ounce, camphor, two drachms, chloroformi, four drachms. Mix and apply morning and night, with long continued friction.

For inhalation: Guaiacol, styrone, olei eucalypti, of each two drachms; alcohol one ounce, chloroformi two drachms, mix.

This should be used with a perforated zinc inhaler, for fifteen minutes at a time, every two or three hours during the day. Or the following: Balsam tolu, balsam peru, balsam storax, olei eucalyptus, of each one ounce, alcohol twelve ounces.

Digest for six days and filter, add to this mixture one ounce of beech-wood creosote and one ounce of chloroform. Put fifteen drops on a perforated zinc inhaler and use fifteen minutes every two hours during the day.

Another good inhalant is cold infusion of prunus virginica, four ounces; oil of bitter almonds, two drops; hydrocyanic acid, dilute two drachms; chloroform, half a drachm.

Mix and inhale five minutes every two hours during the day, through a Liforme or similar inhaler.

SPECIFIC HYPODERMIC AND PARENCHYMATOUS TREATMENT.

Hydrargyri chloridi corrosivi, one grain, sodii chloridi, one-half ounce, aqua fervens, dist. four ounces. Mix and filter. Begin by giving five minims subcutaneously into the cellular tissues every day, increasing one minim a day until fifteen minims are reached; then go back to the five minims and increase as at first. I have used this for the last ten years in the various stages of chronic pulmonary consumption. I have also used the solution of chloride of gold and soda as recommended by Drs. Shurly and Gibbs, but I very much prefer this. There is no doubt in my mind but it has a direct effect upon the bacilli in the lungs.

This hypodermic injection can be used per rectum in doses of five drops in half an ounce of water, three times a day, increasing one drop a day until thirty drops have been reached. Then go back to the five drops and increase as before.

The rectum must be washed out with tepid salt water before each injection. Administered in this way it will be taken directly into the circulation unaltered.

The two methods can be alternated in any case where it is not feasible to give it either hypodermically or per rectum: commencing with ten drops and increasing up to thirty, and then go back to the original dose as before. This should be given directly after the three principal meals.

All vegetable remedies should be given in infusions when practicable, made from the fresh bark, leaves or roots, and to every pint of the infusion add one grain of salicylic acid and ten drops of chloroform. As the patient is about to drink it, let him put into every ounce one teaspoonful of glycerine.

The infusion should be made every day and drank cold.

Epidemic medication should also be practiced, using as a base either pure lard, coco butter, petrolatum, cod liver oil, or fresh butter, variously combined with resorcin, quinine, aromatic oils and resins.

I will close by giving one case which I had in February, 1883. The symptoms may, I think, be considered as typical, and the treatment shows in a general way my ideas of the manipulation of tuberculosis.

Miss Page, blonde, aged 21. Family history showed the father and mother to have died of tuberculosis, together with a brother and sister and several uncles and aunts on both sides of the house. She had been ailing for three months when I first saw her. Lost considerable flesh, was coughing morning and night. Sputa frothy, pulse 120, temperature 102° in the afternoon. Had slight hæmoptysis. Percussion showed slight dullness over the apex of left lung and rough respiration. There was intercostal neuralgia and general tenderness over the whole chest. Appetite poor, bowels constipated, urine scant, passing about one pint in the twenty-four hours, with specific gravity 1030. The skin was very dry and scurfy.

I began treatment by giving three grains of hydrargyri chloridimita at night, in the morning two drachms of sulphate of soda in a pint of hot water, and one pint of spearmint tea before dinner and supper, and a borax bath in the middle of the afternoon to be followed by inunction made of four ounces of pure lard and one drachm of oil of bergamot, alternating this with an inunction of resorcin one drachm, dilute alcohol two drachms, petrolatum one ounce, oil of gaultharia one drachm. Mix and use as above.

I ordered a suppository at night made of iodoform twelve grains, coco butter three drachms, creosote and oil of cloves of each two drops. This amount makes twelve suppositories.

For inhalation, balsams of Peru and storax, oil of sassafras, of each one ounce, alcohol twelve ounces. Digest six days, filter and add one ounce of chloroform. Make a paper funnel and place in it a wad of absorbent cotton. Put from fifteen to twenty drops of this mixture into it and inhale five minutes every three hours. For the constipation, infusion of rhamnus purshiana, p. r. n.

I gave the following to the patient after meals as an antiseptic tonic:

Chloride of sodium four drachms, chloride of potassium two drachms, corrosive sublimate half a grain, water four ounces. Give one teaspoonful after the three principal meals, in two ounces of water or aromatic tea.

As an appetizer the following was all that could be wished: Extract cannabis indica six grains, extract ignatia two grains, salicin fifteen grains, phosphate of calcium half a drachm. Make into thirty tablets and take one thrice daily.

This not only created an excellent appetite, but kept the bronchial mucous membranes free from undue irritation.

For the high temperature she had the following: Tincture veratrum viride one drachm, hydrocyanic acid, dilute, one drachm, tincture prunus virginica, four ounces (made from the green bark, alcoholic strength one to six), put four ounces of the bark into sixteen ounces of the menstruum, give of this from twenty to thirty drops three times daily, in water, or an aromatic tea.

The diet was rare meat, not less than one pound in the twenty-four hours, and from that up to three pounds, condensed milk, bread made from cream of tartar baking powder, soft boiled rice, infusion of malt (made in the manner described), pineapple juice and orange juice, plenty of nice butter, fresh cream.

The principles of hygiene that I have formulated were fully carried out.

The patient was under my treatment for six months and perfectly recovered, and is now in good health.

A MIXTURE FOR HÆMOPTYSIS.

Bamberger is said to have approved of the following mixture in hæmoptysis:

- R. Turpentine, ʒʒ ʒ j.
- Oil of sweet almonds, ʒʒ ʒ j.
- Mucilage of acacia, ʒʒ ʒ iv.
- Simple syrup, ʒʒ ʒ iv.
- Distilled water, ʒ v. ʒ ij.

One teaspoonful of this mixture may be given every half-hour.

INSTINCT IN ANIMALS AND INTELLIGENCE IN MAN CONTRASTED.

WITH AN EXAMINATION OF DARWIN'S DICTUM OF THE "MISSING LINK" AND LINNÆUS' DOGMA

"NATURA NON FACIT SALTUS," WITH A FEW ORIGINAL OBSERVATIONS

THEREON.

Read by Title in the Section of Medicine and Physiology at the Forty-Sixth Annual Meeting of the American Medical Association, held at Washington, D. C., May 5, 1894.

BY WILLIAM W. PARKER, M.D.,
OF RICHMOND, VA.

Instinct in animals is a matter of daily observation by every class of mind, and has always been a subject of great interest, nevertheless it seems still little understood. Writers in psychology are not yet agreed even upon its definition.

Ribot, a modern French writer, says it embraces "all those psychological phenomena occurring in animals, and all forms of mental activity, inferior to those in men." A German contemporary says "It is an act conformed to an end, but without consciousness of that end." Darwin's definition is more elaborate, but scarcely more definite; by reason of its length it is more open to criticism. He says "Instinct is an action which we otherwise would require experience to perform, when performed by an animal, more especially by a very young one, without any experience, and when performed by many individuals in the same way without their knowing for what purpose it is performed." This definition is certainly at fault when it claims that actions under the direction of instinct are performed "without knowing for what purpose they are performed." The dog that went once a week many miles to market alone certainly knew for what purpose he went there. The horses in Richmond that quicken their pace at midday when their heads are turned towards their stables, know why they prefer to go in that direction.

It may be impossible in a few set phrases, however carefully considered, to differentiate clearly human intelligence from what we call animal instinct. Their manifestations are so varied and numerous, and so interlocked, that like the lights and shadows in the landscape we cannot say where the line of separation really begins.

Why there should be such reluctance among modern writers in granting intelligence to animals is rather hard to say. The analogy in anatomy and physiology of man and the lower animals is very remarkable. The laws of digestion, assimilation, circulation, etc., are very much the same. We endeavor by vivisection to unravel the mysteries of digestion or indigestion in man.

In the brain of the animal we see analogy in structure; why may not there be analogy in function?

But to return. It seems to me sufficiently defi-

nite to say that "Instinct in the animals is a strictly limited knowledge or intelligence sufficient only first, for self-preservation; second, for the propagation of the species; and third, to secure their usefulness to mankind."

SELF-PRESERVATION.

1. Of self-preservation. Life of life is an instinct universal in man and all animals. The she-bear beats her cubs and drives them up the tree at the sound of the dogs. The "danger cry" of the hen sends her chickens to shelter. Not to furnish the animal with sufficient intelligence to protect itself and its young would have been both a cruel and fatal mistake in the Creator. This point needs no further argument or illustration.

2. An equally fatal error would have been not to make provision for the propagation of the species. To do this requires far more intelligence in the animal than was needful for self-preservation. What man with his teeth and feet can build a bird's nest? Where is the man who can with his hands construct the delicate cells of the honey bee? or spin the attenuated spider's line.

How each cell is measured so that all its sides and angles are equal. What foreknowledge in the squirrel to provide in summer for the wants of winter, and yet how indispensable this knowledge.

There is no end of illustrations in this line, familiar to all who think at all. But let it be remembered that no bird can build for another. Each bee must work in its own hive.

How could the animal kingdom be useful to man without first, a good memory; second, a knowledge of persons; and third, some knowledge of property, but all limited. I think much of the remarkable ability of the horse and other animals to find their way home is due to memory.

But this does not meet every case. Some years ago, I visited a patient six miles from the city; there was a private pathway leading across a field cutting off a mile to the house, shown me by the messenger; it was winter, and the path could be very well seen. Five years after I visited the same patient in the summer; the way was lined on either side by high grass and weeds so that it was impossible to see the path. I was riding the same horse, and I looked hopelessly for the path, but the moment I got opposite to it the horse darted from the middle of the road and struck the path exactly. I could not see it till I got some distance in the woods, and supposed he had made a mistake. Here was a mathematical exactness, marvelous and incomprehensible; it was as exact as the magnet. Can there be any of this magnetic power in animals in regard to the cardinal points? guiding them with unerring certainty? What philosophy will solve this problem? And yet how necessary this exactness. If

the bird, five miles from its nest, did not know its exact locality, how could it ever get the information? There must be no uncertainty here, the least deviation would be fatal to the bird and its young. This knowledge is impossible to man; he, however, can inquire the way when lost. The bird must know certainly, or his creation is a failure. So doth God work! We all have daily illustration how the horse's memory is exercised here in the city; if you visit a patient in the morning and have to pass the same house a dozen times the same day, he will wish to stop every time. This is memory without reason, a low form of intelligence.

An equally important factor in the value of the animal to man is his recollection of persons; the dog knows every one in the family, children and servants, knows them day or night, knows their names and often their voices, otherwise he would be of no value as a guard. He would be worse than useless, he would be dangerous.

3. The animal, to be useful to man, must also have some knowledge of property. I had once a very clever dog. I have seen him kill three moccasin snakes in ten minutes; he would take them by the middle, shake them violently, drop them, pick them up again and shake them until they were dead; to do this successfully and safely required great dexterity. He seemed to know as well as I did that the bite would be fatal and hence he used the greatest precaution. One day threw an old basket up a tree and it lodged there. I tried for some time with rocks and sticks to dislodge it but without success; this dog was with me; he remained under the tree all night and till the afternoon of the next day, fasting and guarding my property.

The dog will take the market basket home and guard it from robbery, but to show the distinction between instinct and reason, if you put rocks and sticks into it instead of beans and beefsteak he will carry it to the cook all the same.

We all know that the shepherd dog knows his master's sheep, and knows if one is missing, and he will protect them with his own life. Is not this "knowledge of property?"

Dogs are very much attached to their homes and will make journeys of hundreds of miles to return to them, and by ways that they never traveled before. Though carried on the cars 300 miles they will return, but not by the railway track.

SOME REMARKABLE CASES OF INTELLIGENCE IN ANIMALS.

Mr. Locke, in his essay on the Human Understanding, gives the case of a parrot owned by a Spaniard in a seaport town in South America, who said to her master, "What are all these officers doing here?" The company was startled, and some one replied, "and what are you doing

here?" The parrot said "I mind chickens," and at once began to cluck like a hen.

A gentleman was once driving into the country and his horse suddenly stopped at a blacksmith shop; his master said, "What is the matter with you, Tom?" and got for answer the uplifted hind foot, a sudden shake and the rattle of a loose shoe.

We had a parrot who, when he stole preserves and heard my mother's footstep on the stairway, would fly to the top of the bed post and begin to cry out with fear before accused of the theft. He was fond of musical sounds, and would take small pebbles, put them into a saucer and toss them up to hear them jingle.

I have a cat that has been in the family for eight or nine years, the only cat I ever fancied. She has three methods of getting into my chamber in the morning, and she always pursues them in regular order, the simplest first, and the most complex last. First, to cry at the door, then to scratch; second, to go back three or four feet and throw herself violently against the door. When this fails she gets out on the front porch where, by opening the slats to the blinds, she can see me in bed, and then she rattles or scratches the blinds to attract my attention. Here is reason, beyond question. I was at a loss at one time to account for her second method, but I think she got this idea from seeing the children chasing each other from room to room in play, and when those inside were holding the door, those without would run against it and push with all their might to get in. The third and last way to enter was due to the fact that the cat had often in summertime, when my window was open, been in the habit of entering my room through it. When a child is badly hurt and cries aloud this cat will run with the other children and get up into the lap of the injured child in apparent sympathy.

Dogs know when they do well and when they do ill; they like praise and dislike censure.

We have all seen the wonderful effects of careful training in some animals; this knowledge is secured by imitation. A child of one year can make great progress in this line.

It presupposes a very little knowledge.

OPINION OF SOME DIVINES OF THE LAST CENTURY.

The idea that the lower animals will be resurrected, as was insisted by many distinguished divines of the last century, is not tenable. We may fairly suppose that animals possess no power of introspection, retrospection, or antispection, if I may coin a word, or anticipation of the future. I use these expressions in their broadest sense. This knowledge would require "abstraction," a power not belonging to animals, as is generally agreed.

IDENTITY.

Can we suppose that the animal has any idea

of identity? I think not. Identity is arrived at by a review of the past, a tracing of one's history backwards link by link, to childhood, and a capacity to join these links, and show their congruity resulting in what we call consciousness. We cannot concede this power to brutes.

INSANITY IN ANIMALS.

Another new question, perhaps, is this: can the animal become insane? I think not, as insanity is the breaking of the chain of identity. If the animal does not have it of course he cannot break it. When broken in man we say he has "lost his mind." He has broken the link that binds him to the past. He has lost his identity and by consequence his consciousness. I use this word in its broadest sense.

Rabies in the animal bitten by a dog is not, pathologically, insanity. It is a blood poison leading always and speedily to death; in the dog himself it is a specific disease not at all analogous to insanity in man.

It is singular how opposed some people are to granting even limited reason to animals. But Job allowed them this in his day. He says "God deprived the ostrich of knowledge and understanding, and hence she foolishly laid her eggs in the sand and the foot of man and beast will crush them." The knowledge of animals to that of man is as zero. It is like the knowledge of A B C to that of the English language. No animal could ever understand one of the simplest axioms in mathematics, which might be said to be below the plane of reason, as they do not need reason for their acceptance. Training of the most sagacious animals through ten generations could not bring one of them up to this point. They have no inventive power outside of their own necessities. None could be made to comprehend the principles of the simplest art or science. The dog and horse of a thousand years ago are the dog and horse of to-day.

This knowledge is stationary; when brought in contrast with man's it seems as nothing; a drop of water to the ocean, a grain of sand to the endless beach, its elements are memory and imitation. There is one exception, and that is their knowledge of places. This is marvelous, as before said, but without this special endowment the whole race would perish with the first generation. Here is wisdom and goodness!

The dog, the horse and the cow are man's three best friends. The dog is the farmer's "night watchman." No bad treatment or change in fortune in his master alienates his affection. A medical friend once said to me, in this connection, I have more faith in my dog than in many men. What in these days of "condensed milk" would the neglected infant do without the cow? The goat's milk is no substitute, as we all know. While fashionable women are turning their backs

upon their own off-spring, willing that they should perish rather than forego the theatre and ball room, the faithful cow is the only recourse. She saves thousands of human lives annually. The absence of milk for one day in London would bring more distress than the failure of Baring & Bro., and a half dozen other big houses.

The horse, "whose neck is clothed with thunder," who mocketh at fear and "smelleth the battle afar off, the thunder of the captains and the shouting," is guided by the whistling lad in the fresh furrow and the little child leads him to the watering.

Having, as we think, defined the limits of animal intelligence, let us endeavor to get an idea of man's mental capacities, and see if there is one or many links between the two. For this purpose I propose a new method of analyzing the human mind or classifying its capacities, or, if you please, giving its dietetics, the food on which it feeds, in which ample place will be found for its powers of imagination, etc. For simplicity it may be regarded as a trinity, but not the trichotomy of the Egyptians and Greeks. The modern theory of Sir William Hamilton is far too complex. In proposing to be original I hope I show no want of respect for learned authority. Too much subservience to authority blocks progress in all art and science as well as in philosophy. It is proposed in this paper to consider the mind, 1st. In its moral perceptions or its power of comprehending moral truths.

2nd. Its immoral perceptions or passions.

3rd. Its cosmic powers or conceptions of the natural world, the Cosmos of Humboldt, including, if you please, all physical science. It is very natural that this last division of the subject, from its vastness, should have been most attractive to mankind. It was visible, tangible, always and everywhere. It could not escape us. The fool as well as the wise man had eyes and hands and must needs use them. But one of the Greek philosophers had the true idea when he said the greatest wisdom was, "Nothe se auton." (Know thyself.)

Moral philosophy is more important than natural philosophy or science. Man's happiness is more involved in this Greek aphorism than in all La Plaiçe's and Newton's discoveries.

The wonderful dome that we carry on our shoulders poised so delicately, is marvelous beyond description and the most marvelous and valuable endowment are its moral perceptions. In its study is involved man's highest happiness. A man must know very little of himself who is disposed to question this proposition. Not only is man's individual happiness involved in it, but the happiness of the entire race.

It is a curious fact that there is no necessary connection between morals or goodness, and intelligence. A man may be a Bacon in learning,

and a debauchee in practice, or, a Jose, in purity and entirely ignorant of even the simplest rudiments of philosophy.

Attempts were made by the Greeks, especially, to define these moral principles, and direct them into right channels, but they always remind me of men groping in the dark, or of one looking through a low power microscope in search of germs, to find only a mass of debris; the closer he looks the greater seems the confusion. "How vast is the field of morals!" It includes the study of the laws of truth, justice, love, faith and all their various products, as mercy, meekness, patience, gentleness, forbearance, honesty, etc. How beautiful is the search for truth in a great criminal case! Astute lawyers, sheriffs and detectives follow a small thread, attenuated as a spider's web, through fens and fogs, over valleys and mountains, over seas and oceans, in the heat of summer and the cold of winter, holding on to this delicate thread till at last it becomes a cord, a chain that binds the strong man in prison walls.

What a golden shield justice throws over innocence when attacked by non-hearted tyranny, or the viper tongue of slander! With what a steady hand does she hold the scales. What a deaf ear she turns to flattery and fame. She heareth the cry of the prisoner and breaks his hands asunder. The cry of the troubled widow, and gives "beauty for ashes, the oil of joy for mourning."

But what shall we say of love? Though I should "speak with all the tongues of men and angels," I could not describe her. The faith that removes mountains is not equal to her; the benevolence (so-called) that would give all its goods to feed the poor, is not her equal. In honor she "preferreth another, she hopeth all things, endureth all things," seeketh not her own, thinketh no evil, rejoiceth in the truth. What more shall we say of her. Love would open every jail and penitentiary, dry every tear, clothe every ragged child, heal every broken heart.

But what shall we say of faith? Faith in your doctrines, faith in your friends, faith in your God. It binds men together with hooks of steel. It has laid delicate women calmly upon the block, and tied them joyfully to the burning stake. But what says the great philosopher, Paul, of it. "Through faith we understand the worlds were framed by the word of God." "Without faith it is impossible to please God." "Faith subdues kingdoms, stops the mouths of lions, quenches the violence of fire." Men out of weakness are made strong, wax valiant in fight, and turn to flight the army of the aliens. The highest compliment ever paid to man by great authority was to men of great faith, of whom it was said, "The world was not worthy." There can be no peace without it, no commercial progress, no domestic happiness, society would go to pieces without it and chaos reign supreme; what need, then, for

the exhortation, "have faith in man and have faith in God." The man who has no faith in the former has no faith in the latter. This is not generally admitted, but can be logically proved. In morals, as in nature, there are grand massive truths as well as microscopic beauties.

Even the Christian world has little idea of what delicate refinement these great principles, Faith, Justice, Love, Truth, the four corner stones of God's great temple, can attain. They can be seen in the look, the tear drop, the tender tone, the sigh, in the infant's tottering step, and the widow's dying smile. They are like four great rainbows, spanning the Heavens, and beckoning us to the skies. And, better still, they are progressive, so that by steady and persistent effort we may attain the dream of the poet and have

"A heart in every thought renewed
And full of love divine,
Perfect, and right, and pure, and good.
A copy, Lord, of thine."

It is pleasant—to change the figure—to contemplate the final triumph of these four sturdy warriors, of God's good Providence, as they march forward to the conquest of the world. Do we not feel the conflict within us to-day in every man, the "war among the members?" Volumes have been and many more volumes will be written on this branch of my subject, but I must turn to the consideration of the second part, to-wit: the immoral perceptions and passions of the mind. Alas! what a foul nest of foul birds! what a den of fierce wild beasts! The great apostle of the Gentiles sums them up thus: adultery, fornication, uncleanness, lasciviousness, idolatry, witchcraft, hatred, variances, emulations, wrath, strife, seditions, heresies, envyings, drunkenness, revellings and such like. Seventeen indictments. Of felony, alas! how many misdemeanors! man's charges against his brother, aye against himself, marvellous honesty! There may be no witchcraft in these days, but there are watered-stocks, futures, and trusts worse than witchcraft.

Suppose it were heralded over the land to-morrow that the people of Paris had become so debauched that no boy under fourteen years could venture from home at night except with a gendarme by his side, without danger of assassination. What horror, what indignation, would fill every man's breast, and yet it has become so well known that it causes no surprise, even in this age of boasted Christian civilization, that no girl, however pure and spotless, can go out at night alone, without danger of an assault, everywhere regarded in the Bible as worse than murder. It will be noticed that of the seventeen felonies above enumerated, this crime stands at the head of the list, while murder is put near the foot. This classification is quite usual in the Bible. He who knew the human heart better

than we ourselves, said, "Let him that is without sin cast the first stone."

Unfortunately for man, he cannot sin without consent, and hence he is responsible. It has been proven that some of the bad pleasures of man cannot be enjoyed without intelligent consent. Animals cannot sin because they have no moral nature, and consequently cannot be immoral, in any sense. The shame sometimes exhibited arises from fear of remembered punishment by their masters. Here there is a bridgeless chasm between man and brute. These human passions are said to be instinct, but while that is true in one sense, yet, as before said, they are intelligent and under the control of a healthy will, and are generally exercised, strange to say, under the protest of conscience, when enlightened. How is it possible to explain this strange incongruity? It finds no analogy in the war among the elements in chemistry. Where is the philosopher who will give us the solution?

But I must hasten on to the third proposition, to-wit: The cosmic perception, or the mathematics of the mind and of nature's laws. While the study of nature has been, as said before, always more attractive than the study of morals, it is nevertheless not so abstract. Nature is tangible, visible, some of her laws are written upon the stones and others in the stars. We find metrical motions in the one and methodical "measures" in the other. To man is given the measure of all the spheres, in the *cirde*, without this there would be no astronomy. The "span" is the unit of measure, the parted fingers the idea of "dividers" and angles, in mathematics. Without the eye or without the hand there would be no art, refined or gross, but without either, what worlds of beauty were built by Milton. We degrade ourselves when we exalt the natural above the moral. Nature gives no help to morals, virtue seems not a child of earth.

But let me hasten to the main object I have in view, to-wit, the contrast between animal and human intelligence. There can really be no comparison. It is a matter of contrasts of antithesis. In the animal, intelligence is limited; in man unlimited.

In the animal, intelligence is X; in man the great complex problem of mathematics. In the animal, intelligence is a drop; in man the ocean. In the animal it is a single thread; in man the bolt of cloth. In the animal it is only one stone; in man the great edifice. In the animal there is no identity; in man perfect identity. In the animal no morality; in man it is the highest quality. In the animal satisfaction with the world; in man dissatisfaction. In the animal congruity; in the man incongruity. In the animal no progression; in man endless progression. In the animal insanity is impossible; in man quite common. We are surprised at the tricks of animals and infants

simply because we did not expect any intelligence.

To say, therefore, with Darwin, that there is one link or two "missing links" between animal and human intelligence, is to speak without reason.

Man's highest qualities or perceptions have no existence even in embryo in animals. You cannot weld wood and iron, the chain must be of the same material. A few changes in the anatomy of the chimpanzee would make him a man in form, but what changes in his capacities, would make him man's equal in intellect. One is the intelligent master, the other the ignorant slave.

A block of wood may be of the same shape as a block of marble; a piece of glass, of the form of a diamond; the form of an object has nothing to do with its quality or character.

Other animals besides the chimpanzee have similar organs to those of men; this is true of birds also; the pattern may be the same, but the material without one item of resemblance; one might be of brocade, the other of paper.

Linneus' dogma, "*Natura non facit saltus*," may be true of the vegetable kingdom, but finds one notable exception in the animal kingdom. I do not think that it will ever be proved that any fortuitous concurrence of atoms, or arrangement of cells, can produce moral intelligence.

It is not proposed in this paper to discuss its origin, but I would respectfully call attention to the Psalmist's reasonable answers to his own three pertinent questions, to-wit: He that formeth the eye, shall he not see? He that planteth the ear, shall he not hear? He that *taught man knowledge*, shall not he know?

But to conclude: I have endeavored to show that animal intelligence is zero; to multiply it by itself you have zero.

I have also said it is strictly limited, and if multiplied by itself the result is limited. But the powers of the human mind are unlimited; not one, not a thousand links can bridge the chasm between the intelligence of animals and the intelligence of man.

TWO INTERESTING CASES OF FORCED RESPIRATION.

Read in the Section of Practice of Medicine and Physiology at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May 22, 1891.

BY GEORGE E. FELL, M.D.,
OF BUFFALO, N. Y.

Sunday morning, March 1, at 3:20 A.M., I was called to the residence of Dr. Harrington, on Franklin St., and there found a young lady who had taken a large dose of morphine. At 3 A.M., Mr. Harrington, Sr., had noticed stertorous breathing. He arose, looked at the patient, but concluded that it was nothing more than a very

deep slumber. The condition continuing, however, he called Dr. Harrington, who, examined the patient, finding her in a comatose condition, cyanotic; pupils markedly contracted; and a bottle of morphia upon the table. She had written two or three letters which clearly indicated the cause of the trouble.

I immediately proceeded to forced respiration with the face-mask, which resulted in overcoming the cyanosis and producing an improvement in the heart action. We continued forced respiration with the face-mask until 6:30 A.M., when it was observed that the cyanosis was again increasing, and the condition of the patient growing more and more desperate. No evidences of consciousness were present. By hollowing into the ear, ocular reflexes were noticed in a contracting of the orbicularis muscles. There appeared to be no hope of recovery at this time.

With Dr. Harrington's assistance we made tracheotomy, and inserted the tracheotomy tube, as arranged for forced respiration, into the trachea. Connection was then made with the apparatus, and forced respiration kept up. The improvement on the employment of forced respiration per tracheotomy, over that produced by the face-mask, was evident. The chest movements were greater, and the results were more satisfactory in many respects. However, of so serious a nature was the condition of the patient at this time that not one present expected other than a fatal termination. No pulse existed at either wrist; auscultation could detect no heart movement, either on the part of Dr. Harrington, myself, or the students present. Two conditions, however, appeared to indicate that life was not extinct. The pupils continued contracted, and cyanosis did not supervene. The glassy stare of the eyes was present, and outside of the two favorable indications mentioned, it appeared that death could not be far off. At this point Dr. Harrington's father made the remark that if this young lady was made to live, it would be indeed a "miracle." However I kept up the forced respiration, saying that I would do so a little while longer, "just for the fun of it." In a short time auscultation on the part of Dr. Harrington gave us the satisfactory information that the heart was beating. In the course of a few hours these reflexes were more and more marked, and consciousness supervened. Forced respiration was continued through the forenoon, and until quite late in the afternoon, making some twelve to fourteen hours of continual forced respiration before the patient could be allowed to breathe for herself.

She has made a good recovery.

In this case artificial respiration would at no time have been of any avail to the patient.

Oxygen gas used.

Sunday, March 15, at 11:30 A.M., I was called

to attend Joseph Altieri. A prescription containing phenacetin, morphine and cocaine, in small quantity, had been prescribed by the attending physician, for neuralgia of the stomach. The patient had taken repeated doses, without regard to instructions upon the prescription, until a large poisonous dose of these very dangerous drugs had been taken. At 11:30 A.M., forced respiration with the face-mask was commenced, and quickly overcame the marked cyanosis, which was intensified, undoubtedly, by the phenacetin. With the face-mask forced respiration was kept up all the afternoon, the patient at times becoming conscious. The cyanotic condition seemed, however, to increase, owing to the base of the tongue falling back and occluding the larynx. A ligature was placed through the tongue, and the organ was pulled well up, with the result that the lungs were more readily inflated.

In this case oxygen gas was administered, in connection with the forced respiration apparatus, it being supplied in greater or less quantities, as seemed to be desirable. At times the amount of air passing to the stomach and the bowels was so great as to markedly distend them, thus interfering to a certain extent with the inflation of the lungs by the forced respiration, and indicating one of the difficulties to be met with in forced respiration with face mask. In the afternoon the patient became comatose, and responded very little to the respiratory work. During the evening it was evident that the patient was not progressing satisfactorily, the influence of the poisons being peculiar in their action, there not appearing to be any elimination of the drugs—although the catheter was used as often as was necessary, and the antidotes which seemed to be indicated, and stimulants, such as digitalis and alcohol, injected hypodermically. At 10 P.M., Sunday night, I made tracheotomy, and forced respiration was then kept up by the direct method. The result, as in the former case, indicated the very great readiness with which the method could be used in the direct inflation of the lungs, and the patient was apparently holding his own. I left for home at 11 P.M., trusting that the patient would be in good condition in the morning. An army of students was present to assist in the work of respiration, and with Dr. Harrington they kept faithfully at work through the night, until 5:30 in the morning. At this time the patient was breathing with comparative ease, and the prospects looked encouraging. However, a spasmodic contraction of the stomach occurred; its contents were ejected with force. Every effort was made to prevent any of the vomited matter from passing into the lungs, but the spasm resulted, however, in the ceasing of the action of the heart; and the labor of eighteen hours was thrown away.

The necessity for something other than manual labor in the forcing of a column of air into the lungs, was strongly demonstrated in this case. Although there were plenty of persons present, what with the students and the relatives of the patient, who performed all the labor required, no one who has not witnessed a case of forced respiration can really appreciate the amount of energy expended in respiring for a human being, be it even so easy comparatively as by the method used in forced respiration.

This is the first extended case in which oxygen gas was administered in conjunction with the forced respiration. The results were satisfactory, but the odds against which we were fighting—the combination of deadly drugs which had been taken—were too much for even an expectation that success would crown our efforts. With morphia alone in large quantity, I believe the patient would have been saved.

But these cases have demonstrated again all that has been claimed heretofore as to the value of forced respiration; and I repeat that the physician who has not seen the results of forced respiration, cannot conceive, even with his knowledge of physiology, its value in the resuscitation of human beings in asphyxia, generally.

TUBERCULIN.

ITS VALUE AS A SCIENTIFIC DISCOVERY, APART FROM ITS THERAPEUTIC IMPORTANCE; TOGETHER WITH A CONSIDERATION OF THE MOST RATIONAL MODE OF EMPLOYING THE PRINCIPLE INVOLVED IN IT.

Read in the Section of Practice of Medicine and Physiology, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May 3-8, 1891.

BY S. K. JACKSON, M.D.,
OF NORFOLK, VA.

Whatever may be the estimate formed of Koch's lymph—whether or not it shall be determined to have a curative influence in the class of diseases for which it has been proposed, it must be recognized as of incalculable value in illustrating, or rather, I should say, in demonstrating, the truth of one of the most important principles of biological science.

It is running but little risk to prophesy that this generalization will, before long, revolutionize the practice of medicine, by compelling a resort to Nature's mode of curing disease; that is, by using the means that Nature employs for inhibiting or arresting the life-processes of organisms which are known to be the causative factors in the production of certain diseases.

While recent clinical records have caused a great distrust in Koch's method as a safe remedy

in pulmonary tuberculosis, no one has doubted, or questioned, its power of producing a rapid necrosis of the diseased tissue. The *modus operandi* by which this necrosis is effected, is the important physiological and philosophical fact which invests it with the value which we now propose to consider; and if itself should not prove to be the efficient curative agent for which we have been looking, it furnishes a most valuable suggestion for the treatment of this most refractory condition, and confirms the theory which was first enunciated by me some twelve years ago, and upon which is based the practice which I have pursued ever since, and with most remarkable results.

If tuberculosis were a self-limiting condition, and conferred an immunity from a second attack, then Koch's lymph would be of inestimable value as a prophylactic, and second only to vaccination as a blessing to the human race. But as such is not the case, it must, for the present at least, be relegated to its position as a scientific fact, without the practical value it was at first supposed to possess, so far as is known at this time.

Let us, for a moment, consider the nature of Koch's remedy, and see how far it conforms to the biological law to which I have alluded.

It is a poison formed as a consequence of the life-processes of the bacillus tuberculosis, preserved in glycerine to prevent further decomposition. In other words, it is the effete excretory product of the microorganism causing tuberculosis employed for the purpose of inhibiting its life processes, and thereby arresting its work of destruction, on the principle, or in accordance with the law, that "no organism can live in its own excreta."

I acknowledge that this is not the universally accepted idea concerning it, for Dr. Solis Cohen, in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, xvi. 11, p. 370, speaks of it as the product "of a mutual reaction of the bacillus and the tissue, dissolved in glycerine, and by the formation of which the microbes are deprived of food and starve to death." This ignores the poisonous effects upon the microbes.

That we may be sure of giving a fair interpretation of it, let us refer to Koch's own account of its nature and *modus operandi*, and use his own words.

In his November paper, Koch gives the following explanation of the process: "The tubercle bacilli, produced when growing in living tissue, the same as in artificial cultivation, contain certain substances which variously and notably unfavorably influence living elements in their vicinity. Among these is a substance which, in a certain degree of concentration, kills or so alters living protoplasm, that it passes into a condition that Weigert describes as a coagulation necrosis. In tissue thus become necrotic the bacillus finds

such unfavorable conditions of nourishment that it can grow no more, and so it times dies." Or as expressed in McNeill's translation of Koch's January paper: "The bacillus then finds such unfavorable conditions of nutrition that it is unable to keep on growing, and under certain circumstances even dies off." That he considered the microbe effectually disabled, if not killed, is evident from the closing words of his August paper. He says: "I am only able to draw one conclusion from these researches, viz.: the possibility which exists from this way of paralyzing absolutely the action of the microbes in the animal."

Were it not for testimony which he subsequently furnished, we might suppose that he had changed his mind by the time his November paper was published; in this he says: "The necessary histological investigations are not yet complete; but this much is certain, that there is no question of a destruction of the tubercle bacilli in the tissues, but that only that the tissue enclosing the tubercle bacilli is affected by the remedy."

We might be in doubt as to the meaning of this faulty English, were it not for the following emphatic declaration: "To recapitulate, the remedy does not kill the tubercle bacilli, but the tuberculous tissue, and this gives us clearly and definitely the limit that bounds the action of the remedy."

It is difficult to reconcile this statement which may be attributed to incomplete histological research with the following: "As a rule, the number of the bacilli decreased only when the expectoration began to present a mucous appearance. They then entirely disappeared, but were again observed occasionally until expectoration completely ceased."

This positive assertion is worth more than mere speculation, and leaves us in no doubt as to the death of the bacillus.

In reference to this point Dr. Ernest Laplace remarks: *Times and Register*, January 17, 1891. "Koch has determined that the treatment does not destroy the bacillus, the seed of the disease. What is destroyed is that which has developed from the tissues under the irritation of the bacillus. If the remedy only did this, Koch's object would not be reached." And further: "There is one means left for curing the tuberculous process; that is, that the lymph should so act upon the system as to render it unsuited to let the bacilli of tuberculosis develop in it." "In other words, Koch hopes that the remedy will confer immunity against tuberculosis in man, as he says it does in the guinea pig." And further: "We have all reasons to surmise that the lymph is directly or indirectly the result of cultures of the bacillus tuberculosis."

From these extracts from Koch's several papers it is evident that he considered this substance,

which is the result of the life-processes of the bacilli (their excreta), as furnishing a medium unfavorable to their nutrition, and even, sometimes, causing them to die. This conclusion, it will be seen, corresponds precisely with the law enunciated by me in the year 1879.

In my report on *Advances in Hygiene*, etc. (Trans. of Medical Society of Virginia, 1879, p. 56), occur these words: "It is not wholly for want of pabulum that it dies, but it is actually destroyed by the products of the decomposition, whatever be the products, etc." In a foot-note I claim that this furnishes "an additional indication for the employment of ammonia in the treatment of typhoid fever, not only to restore the nitrogenous waste, etc., but also to saturate the system with what the organism producing the disease is known to exhale, and thereby diminishing or destroying its vitality." And further, on page 72, in speaking of the gaseous products of putrefaction and fermentation, I say: "These gases may, if the air be sufficiently saturated with them, arrest the decomposition of which they are the result, by destroying the life of the organism, on the principle stated, viz.: that life cannot be sustained in its own excretions."

Again, in my report on *Advances in Practice* to the Medical Society of Virginia in 1883, published in the *Transactions* of that year, p. 66, occurs this passage, p. 75: "If the theory, first enunciated by me, as far as I know, at our Alexandria meeting (in 1879), be a law, this may furnish us with a guide in the selection of our germicides. If it be a law that 'no organism can live in the effete products of its own life, in its own excreta,' then the most rational means of destroying it, would be to saturate it with the resulting products of its vital processes; for, as has been shown, these products become poisons and arrest the growth and development of the organism which generated them, and finally cause their death." Then follow some illustrations of this principle, e.g., the effects of carbonic acid on the organism producing fermentation—of sulphuretted hydrogen, of ammoniacal gas, etc.

Again, this principle is further insisted on in a paper on "The Treatment of Typhoid Fever," read before the American Medical Association (Washington meeting), in 1884, in which paper, published in *THE JOURNAL*, of August 16, 1884, p. 183, occurs this passage:

"In a paper recently read before the Virginia State Medical Society, I have contended that we are furnished with a key to the selection of germicides by a law which, as far as I know, I have been the first to enunciate. I claim that it is a law that no organism can live in its own excreta, in the products of its own vital processes. When carbonic acid gas is the excretory product, how certainly does carbonic acid destroy the life that produced it. If alcohol be the product of

the life-process, what better agent have we for arresting that process than alcohol itself? and how generally is it used for that purpose! If sulphuretted hydrogen be the exhaled excretion, all acknowledge the efficacy of sulphur and its compounds in arresting the decomposition giving rise to it. So also, if ammonia be the result of the vital processes of an organism, as is claimed in the case of typhoid fever, then by this law, we have a right to infer that ammonia is the proper and efficient germicide. This furnishes us with an additional indication for employing the salts of this nitrogenous base, for it not only supplies the nitrogenous waste, as we have contended, but also destroys the vitality of the organism which causes it."

In an editorial of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, October 10, 1885, p. 405, occurs the following allusion to this doctrine, with an extract from the same paper on the *Ammonia Treatment of Typhoid Fever*: "Why or how it (nitrate of ammonia) reduces the temperature of enteric fever, cannot be definitely stated; but he (Dr. Jackson) thinks that 'it is by inhibiting the life-processes of the microbe, by saturating it with the products of its own life, thus either crippling its vitality or altogether destroying its life, on the principle enunciated by him several years ago—no organism can exist in its own excretions, the product of its own life-processes.'"

I hope I may be excused for producing another extract on this important subject.

In a paper read before the Ninth International Medical Congress of 1887, on "Natural Agencies inhibiting the Life-processes of Pathogenic Organisms, considered with a view to their therapeutic employment," published in the *Transactions* of said Congress, Vol. iii, p. 396, I have insisted on this as one of these agencies, thus: "Next to the destructive effects of extremes of temperature, the most clearly recognized natural agency which affects the vitality of pyrogenic organisms is the production, in the medium in which they live, by means of their vital processes, of substances which are poisonous to them and cause them to die; that is, they are killed by the products of their own life-processes." "No living being can long be kept alive when so confined in the medium in which it exists, as to absorb the products of its own life-processes, its own excreta, etc., illustrated by fish in unchanged water, and by plants cultivated continuously on the same soil, etc. The excretions, then, of all living organisms are inhibitory to their life-processes, and to avail ourselves of this law with a view to its therapeutic employment, requires a minute study of diseases of zymotic origin, and may necessitate a new treatment, directed to the destruction of the particular organism which may be ascertained to be the pa-

thogenic factor in each of them. If any one is disposed to doubt the general proposition upon which this study is founded, let him examine closely any one of the various fermentations, etc.

Then follow instances in which this plan of treatment might be adopted, and also an enumeration of anti-ferments—quinine, claimed to act on this principle; dyspeptic conditions with eructations of sulphuretted hydrogen, relieved by condiments containing sulphur, *e. g.*, garlic, onions, asafoetida, etc., or by the salts of sulphurous acid; the saturation of the system with ammonia in the typhoid state, as there is known to be nitrogenous waste with ammoniacal exhalations. And further, what is now more to the point, in elucidating the treatment of the tuberculous state, I allude to the exhalation of sulphuretted hydrogen from the decomposition of the sputum of tuberculous subjects, which probably suggested Bergeon's plan of infusing into the system this very gas, and also to my own treatment by the free use of the salts of sulphurous acid and the sulphides. I do not know whether subsequent experience has established the efficacy of Bergeon's method, but with regard to my own, the results in eight cases, up to this time, have satisfactorily proved its value.

I admit that the importance of this subject demands a much more extended investigation than I have been able to give it. My inference as to the sulphurets being required, was derived merely from perceiving the odor of sulphuretted hydrogen from decomposing sputa.

That these sulphur salts have a most decided effect upon the hectic paroxysms, any one can determine for himself. In a very marked case which I was able to watch closely, I could readily prevent the return of the hectic chill, fever and colliquative sweating by means of the bisulphite of soda.

The eight cases which I could report as either absolutely cured or decidedly improved up to this time, afford a good demonstration of the correctness of the principle for which I am contending.

While the means above alluded to were my reliance for the control of the hectic condition, other means were, of course, used for general nutrition and building up of the system, the relief of dyspnoea, diarrhoea, etc. Cod-liver oil has been but little used in any of my cases, and alcoholic stimulants only at periods of extreme prostration.

Besides the constant use of the sulphur salts, the chief means employed were Parrish's syrup of the phosphates, inhalations of vapor of turpentine with carbolic acid and iodine, which latter was found to materially relieve the dyspnoea.

This plan of treatment, I contend, effectually arrests the tuberculous process by crippling or destroying the bacillus, without causing the necrosis of the diseased tissue, which is so fatal to the success of Koch's method.

I do not pretend to claim that sulphuretted hy-

drogen is the only exhalation from the bacillus-tuberculosis which might furnish an indication for treatment for which it is not only possible, but highly probable, that a minute chemical study might reveal some other product resulting from the life-processes of this organism, which might suggest some other agent which would be still more efficacious in arresting its vitality and checking its profligate attacks upon the system.

All I contend for is, that it is upon this principle the treatment should be conducted, and upon this line we should search for the agent most destructive to its life.

This also appears to be the conclusion arrived at by Koch and his collaborators, and it is curious to note the similarity of the language employed by them in the year 1890, to that used by me in 1879, at least three years before the bacillus-tuberculosis was discovered.

A PATHOLOGICAL CONDITION OF THE LUNGS, HITHERTO UNDESCRIBED IN THIS COUNTRY, BUT WHICH IS NOT INFREQUENT.

Read at the 15th Session of the American Medical Association, at St. Louis, Mo., 1890, and at the 16th Session at Washington, D. C., May 27, 1891.

BY F. PEYRE PORCHER, A.B., M.D.

ONE OF THE PHYSICIANS TO THE CITY HOSPITAL, CHARLES-TON, S. C.

During the course of a very prolonged service in hospitals, I have repeatedly observed a condition of the lungs which is markedly distinct and characteristic, which I have not seen described.

A full account of this appeared in the *New York Medical Record*, October 19, 1889. I will give here a succinct review of the main features and symptoms, in order that we may decide whether it is only a pathological state, or whether it should rank as a distinct disease.

Patients presented the following symptoms: Dulness or sub-dulness, generally at the middle, lateral or posterior portions of the chest; there was always imperfect respiration; scarcely any rale present, or if so, scarcely disseminated, and generally the subcrepitant, or perhaps there was only rough breathing. The condition was consequent on antecedent morbid states, and was discovered a few weeks before death, if a fatal result ensued. There was not necessarily fever or elevation of temperature; there did not exist evidence of any acute inflammation, or any of the well-known diseases of the chest—no phthisis, pneumonia, bronchitis, pleurisy, emphysema, hydrothorax, etc. The positive physical signs of these diseases were all absent—there were no crepitant, or sibilant, or crackling rales, neither were there pain or rattling sounds. So all the diseases which these signs indicated had to be excluded.

To continue the citation of positive and negative symptoms: The respiratory murmur, though not normal, was not absent, for the lung was still pervious to air; the vocal resonance, or what I prefer to call the reverberation of voice, was slightly affected; some complementary respiration might be present, but this was not very decided, because there was no absolute consolidation. Scarcely any dyspnea may exist, and the cough may be moderate or absent. Hepatization, solidification and asthma had also to be excluded, for there was no absolute dulness, complementary or puerile respiration characterizing the two first, or crepitant râles to indicate the last. The crepitant râle, the fever or the rusty-colored sputa essential to pneumonia were not present. There were no frothy, watery, blood stained expectoration, blueness of lips, lividity, or cold extremities, as in extreme cases of cedemas: no pure hyperemia—for in our cases we have blood and serum mixed; no pulmonary congestion, for there is "no copious, watery, blood-stained expectoration" which accompanies this, which is, besides, an acute disease.

Whenever an autopsy was afforded in such cases, the physical evidences of the diseases above cited were absent, and there was invariably present a large amount of bloody serum exuding from the cut surfaces, and it would flow most freely when the lung was squeezed. There was plainly, therefore, a gross morbid fact which was the chief feature, which had to be noted and accounted for, and which, if a name was required, must necessarily be embraced under such appellation.

The conditions with which our cases would be most likely to be confounded would be the hypostatic congestion, or the hypostatic pneumonia of recent authors, or infiltration of the lungs. But there are none of the physical signs of pneumonia present; and the term infiltration is too vague and undefined—for infiltration may either follow pneumonia or be tubercular, and our cases were neither of these.

We must also decidedly exclude the term hypostatic congestion in the old sense of the term, which implied a condition of stasis just preceding death, dependent upon recumbency, position, etc.

A name was needed for the symptoms which had been isolated, and I long since began to designate the disease referred to as "engorgement of the lungs"—serum being always mixed with blood. I was compelled to the use of these terms because they only were true, applicable, and essential in describing and interpreting the condition.

My cases of engorgement of the lungs exist for days and weeks, and do not depend, as was stated, upon the accidents of position, recumbency, stasis of the blood, age of patient, or want of vitality—for the powers of life are not specially enfeebled.

I published a note in the *American Journal of*

the *Medical Sciences*, as far back as October, 1869, under the caption: "Frequency of Serious Engorgement of the Lungs," but have at last been able to get some confirmation of the probable correctness of my observations in Juergensen's paper entitled "Diseases of the Respiratory Organs" (*Ziemssen's Cyclopaedia*, Vol. v, p. 236). In this Piorry is quoted as having pointed out a distinct form of disease, corresponding in great measure with my own observations as stated above.

It is best to quote what Juergensen says (*loc. cit. Sup.*): "Hypostatic pneumonia, and hypostatic conditions of the lungs, were first recognized as a distinct form of pulmonary disease through the labors of the French writers. Pre-eminent among them is Piorry, who handles the subject with great clearness, and whose teachings are based upon a rich experience. He likewise gave the disease its name." "Piorry proved by experiments that a hypostatic condition diagnosed during life, did not alter its location after death, under the laws of gravitation. As Piorry made his diagnosis long before death, it was evident that this condition did not result during the death struggle. By means of these experiments hypostasis ceased to be a condition of but little pathological significance."

To quote still from Juergensen: "Does an inflammation of the lung actually exist? Is the term 'hypostatic pneumonia' correct? Here we must agree with Piorry, who answered this question in the negative in his nomenclature, and afterwards still further confirmed this opinion." "He calls this form of disease *pneumonie hypostatique*, and gives as a synonym *engouement pulmonaire*."

So I am sustained by Piorry, not only as regards the existence of a special disease, and in the non-existence of an inflammation of the lung, but also in the use of the identical designation, *engouement pulmonaire*, which may be equivalent to "engorgement of the lungs."

Desiring to be brief, I will yet introduce the following from the paper cited above, and which may be compared with my own observations: "The local symptoms of hypostasis demonstrable by physical examination are the following: At first diminished resonance on percussion, beginning at the lower angle of the scapula, and on auscultation a lessening, sometimes a cessation, of the respiratory murmur, which is vesicular, or may be quite indefinite in character. At the point of attack the local fremitus is weak. If hypostasis is complicated with a local catarrh, new features foreign to the former disease will appear. Mucous râles, for example, are usually absent in simple hypostasis. The dulness on percussion and the auscultatory signs, as a rule, extend slowly from below upwards. There is a period at which absolutely no breathing is to be heard over the consolidated portion (Piorry). Then mucous

râles gradually become audible, those in the larger tubes appearing first. In case of a fatal termination extensive oedema of the lungs supervenes, accompanied by auscultatory signs peculiar to that condition." I have not been able to confirm this latter observation, never finding the crepitant râle, which Laennec taught us is distinctive of oedemas, as it is of pneumonia, and the congested area around a hæmorrhagic spot.

Piorry does not mention the causes of the condition he describes. In my paper in the *Amer. Jour. of the Med. Sciences*, I described them as "the result of neglected catarrhs, previously existing bronchitis, or pneumonia in a chronic form, and sometimes the engorgement is partly hypostatic; but this term should be reserved for post-mortem changes, or those occurring just before death."

Both of us, therefore, recognized and marked out a collection of symptoms which are often found associated, but which had not previously been designated as characterizing a special diseased condition. This collection, in my opinion, can have no other name than "engorgement of the lungs;" and all such terms as pneumonias, hyperæmias, congestions, cedemas, etc., must be rejected.

The merit of Piorry consists in his freeing hypostatic processes from the imputation—ancient and deep grounded in all writings—of occurring just before death; and giving it its true place as a diseased condition of variable duration, to be recognized during life.

If my cases of engorgement of the lungs are alleged to be only forms of hypostasis, which I do not believe to be true, I also recognized them as unconnected with position, the decubitus, or the death struggle, defined their *ante-* and *post-mortem* characteristics, as existing and to be studied and treated long before dissolution.

Auscultation and percussion being a true science, founded on variable physical and morbid conditions, there is no obscurity or difficulty about the symptoms furnished by the disease we are discussing. These symptoms, as in every other affection of the chest, arise out of and correspond necessarily with the internal morbid changes which exist, viz.: engorgement of the lungs.

THE MEDICAL LAW OF ALABAMA

The penalty bill, as it passed the legislature, provides that any person practicing medicine or surgery in that State without having first obtained a certificate of qualification from one of the authorized Boards of Medical Examiners of the State, shall be guilty of a misdemeanor, and on conviction thereof, shall be fined not less than twenty-five dollars nor more than one hundred. Provided, that this act shall not apply to any doctor practicing medicine in Alabama who is a graduate of a reputable medical college, and who has complied with the law by having his diploma recorded by the judge of Probate in the county in which he is practicing.

DIGITALIS IN THE FIRST AND SECOND STAGES OF PNEUMONIA.

By J. W. CARHART, M.D., C.M., D.D.,
OF LAMARCA, TEXAS.

MEMBER OF AMERICAN MEDICAL ASSOCIATION, TEXAS STATE MEDICAL ASSOCIATION, AMERICAN MEDICAL SOCIETY, AND BOARD OF THE TEXAS STATE BOARD OF MEDICAL EXAMINERS.

Ziemssen gives 50 per cent. of deaths from pneumonia following measles. He lost one half of his pneumonia patients under one year of age, two-fifths of those from one to three years; and one-fourth of those above three. The ratio of deaths from pneumonia among those of advanced years, and enfeebled by age is even greater. The disease prevails to an alarming extent in the State of Texas, particularly at certain seasons of the year; and as a consequence, I have been led to make somewhat careful investigation into the nature and treatment of the disease, and the cause of the very large death rate amongst us, which, I have no doubt, will equal that reported by Ziemssen. Whilst there are many factors that contribute largely to swell the mortality record in this disease, such as insufficient clothing, uncomfortable dwellings, exposure in camp-life, improper sanitation, inefficient nursing, bad habits as it regards the use of tobacco and alcoholic stimulants, the one I have chosen for discussion in this short paper is not the least of them all. I am persuaded that the use of digitalis in the first and second stages of this disease is responsible for the death of multitudes in my State, Texas; and I hope, through this means, to call the attention of the profession to the subject, and thus save many valuable lives and relieve much suffering.

In order to a clearer comprehension of our subject, it will be well for us, in the first place, to consider the physiological action of the drug in the condition of health. Here we find, not only a variety but a decided conflict of opinion among writers; a conflict which is unfortunate, not to say unjustifiable. There are many established facts, however, upon which most, if not all, writers are agreed.

"Fish placed in a weak infusion of the plant die in spasms, with the ventricle of the heart contracted. Digitalin used hypodermically in frogs occasions a tetanoid rigidity of the muscles and an irregular, tonic contraction of the left ventricle of the heart, with slowness and unsteadiness of its rhythm. The auricle does not seem to participate in this action of the ventricle, but becomes distended as the capacity of the ventricle diminishes. At the same time, the pulse rate declines and the blood-pressure increases. . . . Experimental investigation has demonstrated that large doses of digitalin pro-

duce marked contraction and even a complete closure of the capillary vessels, a condition which necessarily involves an increased blood-pressure in the larger arteries. . . . The auricle does not participate in the contraction affecting the ventricle, but becomes distended by the accumulated blood. . . . Digitalis is held to act on the vaso-motor centre, and thus to produce contraction of the peripheral arterioles."

In small doses, digitalis and its preparations primarily increase pulse-rate and tension, and if continued will lower the pulse-rate without diminishing the tension. The supply of arterial blood is everywhere diminished under the influence of the drug, owing to the tonic contraction of both the left ventricle and of the arteries themselves.

All the heart-muscles are not subject to contraction in an equal degree, under the influence of digitalis, but chiefly those of the left ventricle. It thus tends to obstruct cardiac circulation; and by preventing free passage of blood through the heart tends to produce death from syncope.

It certainly depresses the entire nervous system, if administered in sufficient doses to produce anything like its physiological action; impairs digestion, diminishes urination, retards respiration and interferes with the nutrition of the heart itself.

Digitalis as an antipyretic is valueless. If any antipyretic effects should be produced it would be accompanied by disquieting results, and a tendency to heart paralysis.

The result of various experiments proves that digitalis does not in the least modify favorably any acute inflammation, and especially pneumonia, pleurisy and pericarditis; but that, on the contrary, it exposes the patient to the risk of sudden death.

It is now in order for us to get as clear an idea as possible of the pathological conditions in pneumonia that we may understand the effects of digitalis in the first and second stages.

It will not be necessary, for our present purpose, to discuss the fine distinctions that are made in this disease, such as bronchial pneumonia, catarrhal pneumonia, and lobular pneumonia.

The term broncho-pneumonia will sufficiently indicate the form adapted to our purpose in this discussion.

The lungs are made up of bronchi, air-passages, alveoli, pulmonary pleuræ, and connective tissue stroma, containing blood-vessels, lymphatics and nerves.

In pneumonia, of the type under consideration, the common course is for the inflammatory invasion to proceed from the larger to the smaller air tubes, thence to advance into the finest, to the capillary bronchi, whence it communicates the inflammation to the terminal air passages, and alveoli.

This process of invasion may be almost simultaneous and rapid; or it may take several days or weeks.

The result, sooner or later, is the involvement of the bronchi and more or less lobules of pulmonary hepatization and possibly atelectasis.

I am aware that from a strictly pathological standpoint we may not speak of the three stages of the disease as the stage of inflammation and engorgement, the stage of infiltration and red hepatization, as the result of engorgement; and the final or third stage of resolution, in favorable cases; or that of gray hepatization and possibly atelectasis premonitory of dissolution; and yet, clinically, this division would seem to be correct, and to be very serviceable.

In order to a fuller understanding of our subject, let us consider the condition and function of the lungs in the first and second stages of the disease; and the resultant effect upon the circulatory apparatus.

In the early stages the bronchi contain more morbid secretions in the form of clear viscid mucus, whilst in subsequent stages they are filled with creamy pus. There are sometimes found subpleural accumulations of somewhat inspissated, yellow secretions, contained in dilated alveoli, or in small globular dilatations of terminal bronchioles. They are probably caused by the secretion of particles of bronchial secretions into the alveoli in the forcible inspiratory effects which follow paroxysms of cough.

"The lung itself," says Pepper, "exhibits, associated in varying degrees, congestion, œdema, emphysema, collapse, and pneumonic consolidation."

Juergensen showed, twenty years ago, that there was stagnation in the lungs rather than an active hyperemia, which results in the weakening of the heart. He also showed that the lung consolidation not only presented more or less obstruction to the pulmonary circulation, and hence necessitated increased action on the part of the right ventricle; but owing to the diminished respiratory surface, this ventricle is obliged to do more work in order that the proper interchanges of gases may be effected in the lungs.

It is important for us now to consider the effect of the above conditions of the lungs on the heart and circulation and we shall then be prepared to study the effects of digitalis in these cases.

It matters but little, so far as our present purpose is concerned, whether pneumonia be considered a systemic disease, with local manifestations in the lungs, or whether it be regarded as primarily affecting the lungs with systemic consequences.

We find as a clinical and pathological fact, the lungs engorged, swollen and hot, whatever may be the etiology; with blood stains; followed by hepatization and infiltration, and a consequent

obstruction of circulation in the fine network of capillaries.

As a result of this condition of things we find a lack of aeration of the blood with consequent carbonic acid poisoning of the whole system.

In consequence of the obstruction to the passage of blood through the lungs the pulmonary vein is inadequately supplied even with a partially aerated blood stream. The blood coming to the left auricle and ventricle is hot in consequence of the extraordinary heat in the lungs. This hot, partially aerated blood stream stimulates the heart to greater activity, whilst its nourishment, furnished through the coronary arteries, is inadequate to its overworked condition.

"The longer this condition exists the more rapidly the heart will be overworked. As the irritability of the excito-motor ganglia and the tone of the vagus also reduced by the defective oxygen supply."

Owing to the back pressure, so to speak, upon the venous blood stream, from the right heart, caused by the blood stasis in the lungs, we have extreme venous tension, and intense strain upon the right heart.

In the onset of the disease we have a contracted condition of the capillaries, particularly of the periphery of the body, which adds to the venous tension.

We now have labored respiration, owing to Nature's effort to compensate for the restricted active lung area; we have a diminished, and intensely inadequately aerated blood stream from the lungs, through the pulmonary vein to the left heart—we have a heart stimulated to frightful tension, in most cases, by the overheated blood, and inadequately nourished by vitiated blood through the coronary arteries—we have an inadequate, deteriorated arterial supply, with capillary and venous engorgement.

With this condition of things we are told to give digitalis to relieve the dyspnoea and strengthen the heart.

Dr. A. L. Loomis, writing on croupous pneumonia, in Pepper's system of medicine, Vol. 3, pp. 346, 347 says: "A careful study of the pathology of pneumonia not only leads one to the conviction that venesection must do harm, but it strongly contra-indicates the employment of all those remedial agents which have been used to arrest a simple pulmonary inflammation."

He further says, "Veratrum is claimed to be a cardiac depressant; and this fact should make us hesitate before we administer it in pneumonia. It acts promptly in slowing the pulse but its effects are only temporary, and when used for a couple of days the large doses that are necessary to bring about the desired results interfere with the nutrition of the patient, often causing vomiting and diarrhoea. Aconite is also a cardiac sed-

ative, but my experience with it has convinced me that it is in all respects inferior to veratrum. Digitalis, which may be regarded as a cardiac stimulant, is to be preferred to either veratrum or aconite. It not only lowers temperature, but lessens the frequency of the pulse, steadies it, and produces, in the majority of cases, its well known tonic action upon the heart.

Its use in children is sometimes followed by an intermittent pulse, but it is a symptom of no dangerous import."

Barring the cases of pneumonia in children, in anemic and in aged persons, I would, with all respect for Dr. Loomis, ask him why not practice venesection in extreme venous tension in the stage of engorgement? We are certain that the procedure discreetly used, has saved many valuable lives, and if practiced in New York City would reduce the fearful death-rate there from this increasing disease.

I will now quote an authority of equal eminence with Dr. Loomis, in reply to his theory that medical agents should not be used to lower the temperature in this disease; and against his advocacy of the use of digitalis.

This authority says, speaking upon the very same subject, croupous pneumonia, "In all severe types of croupous pneumonia there are two prominent sources of danger: heart-insufficiency and high temperature. There are, consequently, two prominent indications for treatment, viz.: to sustain the heart and reduce the temperature." The same authority further says, "Digitalis of late years has been extensively used to counteract heart insufficiency, but it is very uncertain in its action in the heart-insufficiency of pneumonia, and has seemed to me more frequently to do harm than good. The nervous element of the heart failure contra-indicates its use."

You may be curious to know who my authority is, so plainly and positively, and, as I think, unanswerably contradicting Dr. Loomis; and I must tell you that it is Dr. Loomis himself writing subsequently to the first quotation I have made from him.

We are told that digitalis reduces temperature, is a heart-stimulant, slows and steadies the heart-action in pneumonia and relieves dyspnoea, and consequently should be used, even in the first and second stages of this disease.

It is yet to be proven that it lowers temperature under any circumstances, except where it kills. It also remains to be proven that it slows and steadies the heart's action in the first and second stages of the disease, and that it relieves dyspnoea.

On the other hand, I affirm, and on the authority of eminent observers coupled with my own experience, that in most cases in the first and second stages it increases dyspnoea, stimulates an already over-stimulated heart, renders the pulse

unsteady and intermittent, as Dr. Loomis has said, tends to produce heart-paralysis, contracts the capillaries and thus adds to the blood stasis in the lungs with increased venous tension and all its consequent train of evils. If pushed in the conditions to which I have referred it will almost inevitably produce death.

Veratria, with morphia and atropia, until the third stage commences, in most cases, slows the heart's action without depression; dilates the capillaries, thus relieving the venous tension and the right heart—relieves dyspnoea—conserves the vital forces—reduces temperature and lessens the inflammatory process.

If there is dicrotic pulse, and especially from the use of digitalis, veratria, morphia and atropia will relieve, as I have witnessed in multitudes of cases.

They should neither be pushed to their unpleasant consequences, since the desired results can usually be obtained without.

THE REPORT OF A CASE OF FATTY URINE ACCOMPANYING AN ABSCESS IN THE RIGHT ILIAC FOSSA—RECOVERY.

Read at the Session of Practice of M. D. Connolly, at the 12th and Annual Meeting of the American Medical Association, held at Washington, D. C. May 15th, 1885.

BY J. P. CONNELLY, M.D.,
OF WILLIAMSTOWN, PA.

Mrs. W., colored, aged 27, born in Pennsylvania, and never resided outside the borders of the State. Gave birth to a living child at 16; has never been pregnant since. Had good health for the first five years following the birth of her child. During the last six years, has had irregular chills followed by fever lasting from two to five days. No disturbance of the menstrual functions. Bowels have always been regular, and she never had pain in the region of the cecum. On Thursday, January 9, 1890, she was taken with headache and backache, and then a severe rigor followed by high fever. I saw her on Saturday, January 11. She had then temperature 104°, pulse 120, a heavy white coat on tongue, and in addition to the general symptoms accompanying fever, complained of a pain in the right iliac region, where a deeply seated tumor, giving an obscure sense of fluctuation, could be felt. It was about the size of a croquet ball, slightly ovoidal in shape, and dipped down into the pelvis, displacing the uterus to the left.

She stated that since Tuesday, January 7, two days before the rigor, she had noticed fat in her urine, and showed me some which contained large broken pieces resembling tallow.

To avoid a possible error, the patient was requested to pass urine in my presence, which was

done. Floating upon the surface of the warm urine, could be seen large quantities of fat, resembling castor or olive oil. It rapidly solidified upon cooling, to the consistency of beef tallow, and was of a yellowish white color.

The amount of urine passed in twenty four hours was 24 fluid ozs. In this the fat, when collected and warmed, measured 4½ fluid ozs., and weighed, when moulded into a cake, 3½ ozs. avoirdupois.

The urine was clear, without sediment, color amber, reaction acid, specific gravity 1020. No albumen, tests used were heat and nitric acid and Heller's test. No sugar.

Fat was passed in about the same quantity for eight days, when a large amount of pus was suddenly discharged with the urine. The fat then immediately and entirely disappeared.

Pus was passed in gradually diminishing amounts for about three months.

The patient slowly improved and in about five months was apparently restored to health, and has remained so to the present.

No cod-liver or other oil had been taken before or during this period.

The blood was frequently examined for falaria, but always with negative results.

So far as my knowledge goes the case is unique, in the amount of fat passed, the time at which it was passed, and in the subsequent recovery of the patient.

In the previously recorded cases, the fat seems to have been passed in small amounts, except in the cases of Dr. Johnson and of Dr. Cushing. Dr. Geo. W. Johnson's case was one of calcareous disease of the pancreas, published in the *American Journal of the Medical Sciences*, October, 1883, p. 427, where the fat is said to have passed in such quantities as to "float when cool in greasy flakes on the surface."

Dr. E. W. Cushing published in the *Boston Medical and Surgical Journal*, February, 1881, p. 242, the report of a case of abscess in the left iliac region, in which, several days after the appearance of foul pus in the urine, "at the end of catheterization pure, clear oil ran out, in volume about one-fiftieth of the urine." This continued, with occasional intermissions, for three days. One week after its first appearance, death ensued. "On opening the abdomen a large, foul collection of pus, containing an abundance of pure oil and large strings and pieces of sloughing fat, was encountered in the left abdominal and iliac region. Near the exit of the left ureter was a small opening communicating with the abscess."

My patient, unlike Dr. Cushing's, passed the fat not during but before the appearance of pus, and it seems impossible for it to have been due, as in his case, to sloughing adipose tissue; because during the passage of the fat, there was absolutely no trace of albumen or pus in the urine.

While unable to explain the phenomenon, it seems to us to have been a pressure symptom, as it occurred only the last week prior to the opening of the abscess, and ceased when the pressure was relieved.

Neither are the conclusions of Dr. Cushing borne out "that such cases are sure to terminate fatally, unless by opening and counter opening, a free drainage and disinfection can be carried out."

THE OPTICIAN AND OPHTHALMOLOGY.

BY GEORGE M. GOULD, M.D.

OPHTHALMOLOGIST TO THE PHILADELPHIA HOSPITAL.
PHILADELPHIA, PA.

The paragraph by Mr. Henry A. Riley, in *THE JOURNAL* of May 2, entitled *Cosmetics and Spectacles in Court*, is one of a thousand illustrations constantly reappearing with sorry monotony, of the fact that when a layman tries to say anything about medicine, he, with the most delicious unconsciousness, takes the side of ignorance and untruth, makes a mess of what he tries to say, and if his words have any weight he injures the cause of scientific medicine. It is a strange fatality akin to that of the success of the patent medicine man, and the enthusiastic acceptance by otherwise intelligent men of the impudent nonsense of homœopathy, faith cure, etc. Mr. Riley's words are few, but as representative of the half-formed opinion of perhaps many others, they should have been excluded from the pages of a journal caring for scientific medical progress, and hence require a dozen words of contradiction.

The first sentence is true, but not as supposed by the gentleman. The optician *does* "hold a doubtful position in regard to the practice of medicine," and it is because homœopathy holds such a position, and because supposedly intelligent people encourage the continuance of this doubtful position, go to an optician who knows nothing about this work for correction of optical defects of the eye, instead of going to one who with the study of a lifetime can learn but a small part of the desirable knowledge on the subject. The "doubtful position" should be ended at once by the enactment of laws on the "narrow, technical theory" that your correspondent tells us the French courts have found right. Until that is done opticians will go on ruining eyes and health, as all oculists have bitter experience almost daily in trying to undo and correct the injury done their patients who have first passed through the hands of the optician.

If he furnishes a customer glasses to cure errors in sight—if he investigates the troubles of the eye, if he determines the errors in refraction and if he prescribes a combination of lenses such as will remedy the affection, etc. The gentleman evidently never heard of the Teutonic maiden who, while

drawing beer, fell into a delightful reverie, imagining all the years of splendor and happiness that would follow if she should marry the Prince. In the meantime the beer filled the pitcher and ran all over the floor.

The trouble all lies in the *if*. In order to be perfectly safe, and also to have a loophole to crawl out of if some ignoramus with fiery eyes avers that he can do it, I will say that there is but one optician in the United States who *can* "give a customer glasses to cure errors in sight" or who is competent to "determine errors of refraction and prescribe a combination of lenses such as will remedy the affection." There is only one optician who can do this; the other ten thousand cannot do it.

The limit of the ridiculous is finally reached in the very amusing supposition that "the optician may be a physiologist." This bit of fiction spoken before a convention of opticians would certainly be considered the joke of the day. It is too absurd to answer. If we seek the fundamental reasons for the delusion into which such logicians as your correspondent fall, we find them somewhat as follows:

1. A complete misconception on the part of the general public, and too often on the part of some general physicians, as to the *value* of eyestrain in our modern life. Without a medical education (and with it the optician would necessarily cease to be an optician), the spectacle-vendor cannot know anything of the pathological relations to the eye and the general system. The eye, it is true, is a camera obscura, but it is a living, not a dead or mechanical, one. Every pair of lenses worn by every person in the world has a medical and pathological significance. This, to be sure, seems to the laity an outrageous exaggeration, but it is *la vraie vérité*.

2. The same mediævalism of logic would deny the medical profession a *locus standi* or justification of existence. If the optician can do all it is said he may do, then the doctor should hand his diploma to the pharmacist and go out of business; because the druggist, as a general rule, is far and away more competent to prescribe the proper drugs in a case of disease than the optician is to prescribe the proper glasses. That may also seem an exaggerated statement, and again it is very truth.

3. It is a sneaking, ill concealed belief on the part of many that this opposition on the part of "allopaths," "the old school," "the blue-mass old fogies," to quackery of all forms, to advertisers, to prescribing druggists and prescribing opticians, is a matter of low cunning, self-interest and envy. Those who secretly harbor such thoughts or feelings simply illustrate their inability to perceive facts correctly. They are victims of their own vanity.

4. If to opticians is to be given the function of

prescribing for refractive errors, the law should require of them, as it does of druggists, an education in their calling, a diploma that they are opticians, if not "physiologists," "pathologists," etc. Viewing the eye simply as a dead camera obscura, as having no other laws than optic laws, I have never seen a pair of glasses prescribed by an optician that were correct. I have had hundreds of suffering patients abused by the optician's supposed ability to prescribe, and never was a single pair of lenses correct optically speaking. They did not neutralize the patient's optical error. There is one optician, of course, who never makes these mistakes. As a matter of fact, with the one exception, opticians enter their calling either from the jewelry business or from the work-bench of the spectacle-maker and lens-grinder. Neither one of these callings, honorable enough indeed in themselves, necessarily imply an education in the laws of optics or the physiology and pathology of the eye.

5. Not only do all errors of refraction have medical and pathological significance, but if the optician is to treat all errors of refraction, he must perforce be a physician; because many diseases, most serious and dangerous ones too, can only be recognized by a physician, are not recognized by the patient as other than a call for spectacles, and could not be recognized by the optician. Every oculist has had instances of glaucomatous patients going to the optician for spectacles. As the disease progresses changes in the spectacles must frequently be made, until finally blindness is the walking monument of the non-existence of the "narrow technical theory" of the French courts, and the dominance of the "broader principle of legal construction" your correspondent hopes will have sway here. *Gott bewahr!*

It seems doubly strange to hear an intelligent gentleman arguing in this way in the face of the fact that the best opticians are ashamed of the hypocrisy and the wrong they are forced to do by the competition of unprincipled spectacle-vendors. An optician of any intelligence and honesty knows he does wrong in prescribing glasses. Even the worst of them are vaguely conscious of the fact. The better class will not prescribe except in cases of presbyopia, and even then free their consciences by advice to go to the ophthalmologist instead. The very highest class of opticians, men of conscience and intellect, will never sell a pair of spectacles except upon a physician's prescription. In this direction lies the elevation of the optician's profession, scientific and humane progress; in the way counseled by your correspondent lies the degradation of the optician's profession, and a return to mediævalism in medicine.

AMERICAN MEDICAL TEMPERANCE ASSOCIATION.

BY T. D. CROTHERS, M.D.,
HARTFORD, CONN.

This Association was organized at Washington, May 7, 1891, in pursuance to call by Dr. N. S. Davis, of Chicago, Ill., inviting all persons interested to meet and confer on the need of such an association. Sixty-one physicians were enrolled as original members, and a constitution and by-laws adopted, a board of officers elected, and thus a new medical organization was auspiciously started.

The purpose and object of this new society is outlined in the following statement offered by Dr. Davis:

"The object of this Association is to advance the practice of total abstinence in and through the medical profession, and to promote investigation as to the action of alcohol in health and disease, and it aims at being a bond of union among medical abstainers scattered all over our country. It admits as members regular medical practitioners who are practical abstainers from all alcoholic liquors as beverages. Members are not required to sign any pledge, but if such for any reason cease to become total abstainers it is expected that they will withdraw from the Association. The liberty of members to prescribe alcohol is entirely uncontrolled."

From this it will be apparent that the central purpose of this society is to study and investigate the action of alcohol as both a beverage and medicine. The only qualification required is to be a regular medical practitioner, and total abstainer from alcohol as a beverage. It will be apparent that the last qualification is more or less a scientific necessity for good work in this field. It is assumed rightly, that all physicians interested in this problem of alcohol should approach it from the scientific side alone, unbiased by any personal considerations of custom or habit, political or religious belief, with no object other than to ascertain the facts concerning alcohol, irrespective of all possible conclusions. This is the spirit and purpose of the Association.

In England a similar association composed of members of the British Medical Society has been in existence many years. Their regular meeting occurs at the same time with the British Medical Association, and the value and usefulness of their work is recognized in all scientific circles. In this country a society called the Association for the Study and Cure of Inebriety has been in existence for twenty years. It is composed largely of specialists and persons engaged in treating inebriety as a disease. While it has done grand work, and built up a very suggestive literature through its *Journal of Inebriety*, it has not taken up the popular medical discussion of alcohol, which this new society proposes to do. These

two societies will be closely allied in both work and purpose. One will have for its object the grouping and harmonizing the diverse theories of physicians concerning alcohol and its action, and the other the study of the inebriate and his maladies.

The Medical Temperance Association in the former work will be most heartily welcomed by all scientific men. The alcoholic problem has reached such proportions, and has become a subject of such intense interest in all political, social, and religious circles as to demand scientific study.

Medical men in every community are called upon to determine the facts concerning alcohol, and the necessity for medical study and agreement concerning the general truths are apparent to every one. For this purpose the Medical Temperance Association invite the cooperation and aid of every physician, not for the propagation of any theory, but for the gathering and grouping of facts concerning the action of alcohol.

The Association is entirely independent of any other object except the purely scientific question of alcohol. The Executive Committee has power to hold meetings in any part of the country where the medical interest seems to demand it. The regular annual meeting will be held at the same place and time of the American Medical Association. Papers and discussions will be presented at this time. While this Association is the culmination of an idea long entertained by Dr. Davis, and held until medical sentiment would fully sustain it, it is apparent that it is an expression of medical advance, of the scientific spirit of the times, that would rise above the theories and precedents of the past for the facts concerning alcohol.

This Association appeals to every physician, not as propagandists, but as scientists, for facts and clinical experience. It appeals to them as the only competent authority to determine the alcoholic problem. It appeals to the physician to guide and direct public sentiment, and to make this Association the great central power for the study and propagation of the facts and laws relating to alcohol, and its use and abuse.

The following are the officers elected for the first year:

N. S. Davis, M.D., President, Chicago, Ill.

For Vice-Presidents, I. N. Quimby, M.D., Jersey City, N. J.; J. B. Whiting, M.D., Janesville, Wis.; F. E. Yoakum, M.D., Shreveport, La.; J. Taft, M.D., Cincinnati, Ohio.

Secretary, T. D. Crothers, M.D., Hartford, Conn.

Treasurer, G. W. Webster, M.D., Chicago, Ill.

For by-laws and constitution, and application for membership, address the Secretary, at Hartford, Conn.

MEDICAL PROGRESS.

ON ACID MEDICATION IN DISORDERS OF DIGESTION. — The pathology and treatment of digestive disorders has of late been engaging the attention of many observers in France. The brilliant writings of G. Sée, G. Lyon, H. Chénier and others have done much to disseminate a more thorough knowledge of the causation of dyspepsia. In this matter Germany was, until recently, far in advance. The "French treatment" was far too uniform, and sufficient allowance was not made for the many varying forms of the disease. The routine treatment was either to send the patient to Vichy for a course of the waters, or alkalies in some other form were prescribed, to counteract the "acidity." Of course, many derived much benefit from these measures, but in others they failed completely. In order to understand the principle of the modern treatment, the following physiological details must be understood: The granular cells of the stomach form a substance named *propepsin*, which is secreted continuously, and in presence of the gastric acid is converted into pepsin. This pepsin is used up during digestion, and one of the most frequent disturbances of the process is due to the fact that, although the supply of propepsin is practically inexhaustible, yet the gastric acid may not be secreted in quantity sufficient to convert enough of this into pepsin. Both propepsin and acid are necessary for digestion; neither is of use by itself. If there be excess of functional work and increase of total acidity, we are in presence of a "hyper-hydrochloric" dyspepsia. This condition is probably rare, and only occurs under special circumstances, as in ataxia and some other neuroses. Diminution in the quantity of acid, "hypo-hydrochloric" dyspepsia, exists in the greater number of dyspepsies, the first effect of chronic disorders of digestion being to weaken the chemical operations of the stomach and to diminish the gastric acid. This diminution may even go so far as to lead to its complete disappearance, "ana-hydrochloric dyspepsia," which occurs principally in neurasthenia, and in the later stages of cachexia from cancer of the stomach, etc. As a consequence of the diminution of acid we have fermentations occurring, leading to pain, flatulence, vomiting, and the other well-known symptoms of dyspepsia. These facts once ascertained—and methods for determining them have already been described in our pages—it naturally occurs that the correct treatment is to supply the stomach with the acid in which it is deficient. The problem is, however, by no means so simple: we must not lose sight of the other agents—mucus, rennet-ferment, duodenal secretion, etc., which may also be subject to morbid alterations. Atony or hypersthenia of the muscular tissue, leading

respectively to dilatation or hyperæsthesia, give rise also to their own peculiar train of symptoms. With the increase in our knowledge, we must not shut our eyes to all these and many other conditions, which would certainly not be uniformly benefited by acid medication.

Indications for Alkaline Medication.—Until recently the plan of treatment most in vogue in France has been quite the opposite to this, and alkaline medication has been the method *par excellence*: régime, alkalies, artificial ferments, tonics, laxatives, Vichy water, etc., have benefited many. But at least half receive no benefit from this plan, and others who get temporary relief are not freed for long from their old enemy. Still, there is a class of cases which will be cured by such treatment. Imperfect mastication, privation, overwork, mental anxiety, or an excess of some sort, may have been followed by flatulence, vomiting, etc., and the patient seeks advice. Here the production of acid is diminished, but the glands themselves may be healthy; and in eight cases out of ten they only require the stimulus of an alkali to make them secrete their acid in the proper quantity. In these temporary conditions alkalies are the true remedy.

Indications for Acid Medication.—There is another class of patients who say that they are rheumatic, and only digest well when there are pains in their limbs. In their own language, "their rheumatism flies to the stomach." Such are the patients with *gastric catarrh* from excessive secretion of mucus and duodenal juice. This fluid, if secreted in too great abundance, forms a coating over the gland surfaces, interposing itself between these and the food, and thus weakening or abolishing the power of the gastric juice. No amount of alkaline medicines will be of service—they are victims of the "rheumatoid diathesis," and urgently require acid treatment. The condition has nothing to do with rheumatism properly so-called, and is produced especially in the inhabitants of damp and cold climates like our own. Its symptoms are as follows: Uniform whiteness of the tongue, anorexia, wasting, and loss of strength; digestive troubles, with or without vomiting; alternate constipation and diarrhœa; wandering pains, rendered worse by changes of temperature; frequent coryza, pruritus, and skin eruptions; no true rheumatic antecedents. To such cases strong mineral acids are a necessity. Others to whom it is almost equally useful are the patients with dilated atonic stomachs, which allow of fermentative changes; neurotic and anæmic girls; old men with enfeebled gastric powers; the anæmic dwellers in tropical climates. Such cases often improve remarkably under acid treatment.

Contra-indications of Acids.—The conditions in which acids are formally contra-indicated may be thus enumerated: "Hyperchlorhydric," pure

dyspepsia, irritative dyspepsia, febrile or inflammatory affections, gout and rheumatism, milk diet.

How to Employ Acids.—As hydrochloric acid was found to be the natural acid of the stomach, it was naturally thought that this would be the best to use. In practice, however, it has been found that its powers fall far short of what might be expected. Small doses are useless, and large doses are both inconvenient and irritating. Bonchard gave as much as 5j of strong acid daily to his patients, diluted in a quart of water, and this was often the minimum efficient quantity *per meal*. Others tried vegetable acids—lactic, tartaric, acetic. All these, as might be expected, did nothing but harm. *Aqua regia* is much employed in this country, and enormous doses are often taken with benefit. Some patients, however, cannot stand this, and the author prefers a compound acid prepared in the following way: R. Acid sulphuric (pure), 28 pts.; acid nitric (pure) 8 pts.; spt. vini (800°), 180 pts., by weight, to be mixed gradually in ice. This is his "*acide sulphonitrique rabelisé*." It should be prepared long before required for use; in fact, the older the better. No violent reaction should be allowed to occur during its preparation, and the product when ready for use will contain sulphovinic acid, and a small quantity of nitric ether, which gives it a most pleasant odor. The dose is about 20 drops, after meals, given in water, wine or beer. According to the author no acid gives better results than this, which agrees well whenever acids are indicated. —*Bull. Gén. de Thérap.*

COMBINATION OF PARAFFIN WITH LANOLIN.—Paschkis has found that the special advantages of lanolin are increased when diluted with paraffin. The formula which he found best for a basis is:

- R. Lanolin 66 parts.
- Liquid paraffin, 6 parts.
- Ceresin, 1 part.
- Distilled water, 65 parts. ㊄.

INFANTILE CONSTIPATION.—Bonchut employs the following syrup:

- R. Podophyllin, gr. j.
- Alcohol, f5jss.
- Syrup althæa, f5jv. ㊄.
- S. Dessertspoonful daily.

—*Union Médicale.*

FISSURED NIPPLES.—Dr. Barton C. Hirst (*Univ. Mag.*, March, 1891) suggests the following application:

- R. Bismuth subnitrat.
- Olei ricini, āā ʒj.

The nipple and adjacent skin must be carefully cleansed, and the ointment then rubbed on liberally.

SATURDAY, JUNE 6, 1891.

MASSAGE OF THE GENITAL ORGANS.

Objection again comes, from a high authority, to the use of massage in affections of the female reproductive system.

This question admits of two distinct and separate views based upon the results which follow under those of widely different organism and nervous trend. And the query arises: How can we foresee, in a given patient, debilitated by a neurotic condition involving the genital organs, or laboring under some other morbidity more directly touching the structural harmony of the parts, the unfortunate consequences which are sometimes observed, and upon which the strenuous objections rest?

It becomes at once a metaphysical inquiry, and runs off into fields of moral philosophy. The mind and will of the individual, upon whom the restorative powers of massage is to be tried, should first be studied, and from such study the probable outcome is to be weighed. And not alone the present state, but the past life of the patient as well, should be looked into. Questions of delicacy at once present themselves and should have prompt and straight-forward solution.

When the medical adviser can fully fortify himself with a clear, unquestioned knowledge of the entire mental, moral and physical make-up of his patient; when, so far as the patient is concerned, he feels there is nothing to fear from the application of massage, but that on the contrary there is everything to gain, then, and not

until then, do we feel there is justification in the resort to this remedial measure.

And yet the half has but been said! The masseur! Here, again, must there be a display of the keenest circumspection. If the physician, after possessing the insight above-mentioned, is to act as masseur, or if massage is to be applied under his *immediate* supervision, then we have but little to add. Conscientiousness here is the outgrowth of the previous carefulness. If, however, a professional masseur must be selected, under whose charge the patient is to quite entirely rest, then the two-fold character of the case, and the physician's responsibility, becomes at once apparent.

Here, again, must a solution of the mental and moral integrity of an individual be made, not in the weakness of the body, but under the condition of physical strength. Here, as well, must there be a diversion of will power into paths leading away from the sensual. Here, again, must there be the buoyant feeling of hope, together with that determination towards success in the relief of the patient which plays so important a part.

Too much attention can scarcely be given this subject of the proper and peculiar fitness of the operator; and when this, and the other factors, are duly considered we feel that this system of treatment will be largely bereft of the odium which now surrounds it.

THE WATER WE DRINK.

There is no problem in science more definitely settled, than the one pertaining to the drinking of impure water as a cause of enteric disease. In the large cities, efficient boards of health with skilled men employed as chemists and sanitary officers stand as watchful guardians over the water supply of the people.

In country districts the conditions are quite the reverse; there are neither health boards, nor paid sanitary officers, and usually the only man in the vicinity who has any knowledge of the subject is the neighborhood physician, and upon him devolves a solution of all causes of preventable disease within the territory in which he labors.

In many parts of the country typhoid fever and dysentery appear with the same regularity as

the seasons, and always with the variability of the water supply. Frequently the priceless spring is located on a little lower level than the farm-house and barn-yard; and although it may bubble forth in a stream of clearest crystal water, may be so laden with poisonous microbes, as to become the involuntary purveyor of the germs of disease and death.

Contaminated water may be the only drink of the milk cows and through this channel produce and foster an epidemic of disease.

Physicians engaged in country practice have many opportunities for making valuable observations in this direction, while such studies enable them to become educators of the people.

A "HEALTHERIES" AT NEW YORK.

An imitation of the London Healtheries has been set on foot in New York City, having its offices in the vicinity of Madison Square. Its projectors claim that while the primary operations of the Healtheries will be directed toward the procurement of a purer food-supply, the general influence of the movement will be exercised over all departments of the public health. The company intends to have exact chemical and microscopical examinations made upon suspected articles of food and drink that are offered to the public, and promises to inform the individual consumer, upon application, of the results of such investigations. Inasmuch as a recent Food Exhibition yielded a net profit of \$10,000, it is probable that much of the scientific work above referred to can be accomplished free of cost to the general public. A certain proportion of the annual profits will be laid aside as a fund for a permanent building. A weekly or monthly food journal will probably soon be issued, for the purposes of publishing the results of analyses, and of announcing the new foods in the markets. There will be at the outset a board of three well known chemists; all analyses made for the company must be signed by two or more of the board.

LEPER COLONY IN BRITISH COLUMBIA.

An isolation of all lepers found at large in the towns of British Columbia has been ordained by the Dominion government. An island off the coast, called Darcy's Island, has been set apart

and will immediately be prepared for the reception of the leper colony, composed chiefly of Chinese. The authorities have also ordered that an immediate investigation shall be made as to the alleged rapid increase of leprosy in and about Vancouver, and for that purpose Dr. Smith, superintendent of the leper colony of Tracadie, New Brunswick, has been appointed as an expert commissioner to examine and report the true status of leprosy on the Pacific slope of the Dominion.

SOCIETY PROCEEDINGS.

Medical and Chirurgical State Faculty of Maryland.

Ninety-third Annual Session, held at the Hall of the Faculty, Baltimore, April 28, 29 and 30, 1891.

DR. T. A. ASHEY, PRESIDENT, IN THE CHAIR.

Drs. G. L. Taneyhill, Robert T. Wilson and William B. Canfield, Secretaries.

The ninety-third annual session of the Medical and Chirurgical State Faculty of Maryland was called to order at the Hall of the Faculty, corner St. Paul and Saratoga Sts., April 28, at 12 o'clock noon.

REV. G. F. M. ELLIS opened with prayer, after which the minutes of the previous meeting were read, corrected and adopted. After some preliminary announcements, Dr. T. A. ASHEY delivered the President's Address, on the subject:

THE RELATION OF THE MEDICAL AND CHIRURGICAL FACULTY TO PROFESSIONAL ORGANIZATION IN AMERICA.

The Faculty, one of the oldest State organizations extant, was now entering on its ninety-third year. It had had seasons of prosperity and adversity. In its early life in the colonial history of our country, and later during civil strifes, it had suffered and lost strength. At one time, it practically went out of existence. It had at one time the full power to license all practitioners in the State. This power, which had fallen into disuse, was now entirely lost, through the efforts of irregular practitioners. Whether it could be recovered was a question. If the body could be strengthened, the membership increased, and all the respectable members of the profession of the State brought into unity of thought and action, much of the lost power might be regained. The Faculty was now meeting under auspicious circumstances. The semi-annual meetings recently held in Hagerstown and Cambridge had not only added a large number of new members, but had excited renewed interest in various parts

of the State, the result of which was the formation of local societies. The lessening of the annual dues had had a good effect. The Faculty has always had a very poor home. Now it is well housed, and the library which it possesses is in good condition and well taken care of, but the fact that we only rent this hall, gives it a feeling of uncertainty. We should have our own hall. For this an endowment would be necessary, and this could only be obtained by exciting interest among the members. Such a fund would be started as soon as possible. The future outlook of the Faculty was never better. If we cannot have the power to license, we can strengthen ourselves, and form a respectable State Medical Association.

DR. RANDOLPH WINSLOW read a paper entitled:

INJURIES TO THE KIDNEYS.

A man 33 years old, weighing 170 lbs., while driving very fast, was thrown out, and fell violently to the ground. He was much shocked and nervous. Had much pain in right flank. No bladder symptoms. Next morning there was hæmaturia which lasted a week or more. This with other symptoms disappeared, and then his left scrotum and cord were attacked with great pain, left leg was swollen, phlebitis occurred. These symptoms gradually disappeared and case recovered. A careful study of all the symptoms, and the history of previous cases, pointed to a diagnosis of rupture of the kidney. A sudden and heavy fall may cause rupture of the intestinal organs, and the kidney has been frequently so torn. Extirpation may be necessary.

DR. JOHN D. BLAKE read a paper entitled,

SOME CONDITIONS OF THE URETHRA REQUIRING PERINEAL SECTION.

In the discussion which followed, DR. J. E. MICHAEL said he agreed in some points and disagreed in others. When operation is used as a temporizing means, it is a good thing, and when the instrument is used with proper antiseptic precautions, there is no danger. He is skeptical with regard to electricity. He had been very successful in his operation for deep perineal section, and felt safer in this than in attempting to pass bougies and other instruments, causing chills, shocks, etc. A free incision is attended with very little shock.

DR. J. D. BLAKE said he had been much pleased with the use of electricity, and related a case to prove his point.

DR. L. McLANE TIFFANY read a paper entitled *Indications for Treatment in Malignant Diseases of the Mammary.*

DR. JOHN W. CHAMBERS read a paper entitled *Some Observations on Injuries of the Cervical Portion of the Spinal Cord.*

DR. WM. H. WELCH, of the Johns Hopkins University, then delivered the Annual Address. The subject was

THE CAUSATION OF DIPHTHERIA.

The subject is an exceedingly important one, and has been much discussed in the medical journals of the day, but many of the facts are so new that they can with advantage be brought up again. Although the advantages are principally bacteriological, the points brought out will be chiefly those which illustrate the application of these discoveries to a fuller and more correct knowledge of the nature, etiology, pathology, prevention and treatment of diphtheria.

The questions to be answered are, Is diphtheria primarily local or constitutional in its origin? Are all pseudo-membranous inflammations of the throat not directly referable to caustic irritants, diphtheria? Is there a purely local, non-contagious, pseudo-membranous laryngitis, called croup, distinguishable from diphtheria? Are the pseudo-membranous angine secondary to scarlatina, and less frequently to measles, and some other infectious diseases, identical with diphtheria? Is there any relation between tonsillitis and diphtheria? May diphtheria occur in a mild form as a simple catarrhal inflammation of the throat? Are pneumonia, acute nephritis, suppuration of the glands in the neck, etc., referable to the direct action of the diphtheritic virus? In other words, what lesions belong to the disease and what are complications? Shall reliance be placed chiefly upon local or upon general treatment? These are important practical questions, which a careful study of the disease has not yet answered. Our most recent knowledge on the subject has come through the discovery of the microscopic germ which is the specific cause of diphtheria. There is perhaps no other disease, with the exception of tuberculosis, upon which greater light has been shed, by the discovery of its specific cause, than upon diphtheria. The specific bacillus is called the Klebs-Löffler bacillus. There are three difficulties in the way of proving this. One is the uncertainty as to what is diphtheria, as distinguished from the various angine associated with scarlet fever, measles, etc. Thus different investigators working with different kinds of angine would obtain different results. Genuine cases only should be studied. A second difficulty is the large number of bacteria found in the diphtheritic membrane. It must be determined which of these are constantly, and which are instantaneously present and absent in other conditions. We may presume this is the specific cause, and the presumption becomes a certainty, when we can reproduce the disease experimentally. The third difficulty is to prove that our experimental disease is identical with human diphtheria. As by various agencies we can produce on the mucous membrane of the tonsils, pharynx, etc., a fibrinous pseudo-membrane which is not diphtheritic, we cannot rely on the membrane alone as pathognomonic.

Oertel has demonstrated that the diphtheritic virus is a most peculiar poison to the cells of the human body, and that it produces areas of cell death, not only on the surface of the mucous membrane, but also in deep parts, in various lymphatic glands at a distance from the local lesion, and in the spleen. These changes can be shown by histological demonstration. Now if our suspected germ produces the membrane, and all these changes too, and muscular paralysis, then we have strong evidence that it is the specific cause of diphtheria. All these difficulties were not overcome at once, but it is needless to go over each step. It will only be necessary to say that the Klebs Löffler bacillus has been accepted as the specific bacillus of diphtheria. Dr. Welch and Dr. Abbott had proved this, in a series of cases occurring here. The practical value of this discovery will come later.

The specific germ of diphtheria is a bacillus devoid of independent motility, averaging in length about that of the tubercle bacillus. It presents itself, both in diphtheritic membranes and in cultures, in such bizarre forms that these belong to its most characteristic morphological properties. It grows upon various culture media and in milk. It grows readily outside of the body. It has no spores, but is very resistant, a fact which is shown in the viability of the disease in old clothes, rooms, etc., after many years. Diphtheria is without doubt a local disease. It is only found in the upper part of the membranes. The constitutional symptoms are due to the reception into the system of a chemical substance, a poison produced by the bacillus. The germs are conveyed by bits of membranes, saliva, secretion, etc., but the disease is not as easily spread as scarlet fever, nor is the danger from infection through drinking-water as great as with typhus fever. The toxic substances produced by the bacilli are very complex, and worthy of careful study. The difference in epidemics, mild or severe, is not easily explained. Similar differences are noted in experimental diphtheria. The discovery has not yet reached the diagnostic importance of the tubercle bacillus; that is, it cannot be so easily put to use, but for one skilled and equipped in bacteriological research, or in a large hospital, such a method is inestimable. As bacteriological methods become more generally understood, such means of diagnosis will be used. The angine occurring with scarlet fever, etc., are not diphtheria, as the bacteriological examination would show. Other bacteria are frequently but not constantly found. Diphtheria may be communicated from animals to man, and *vice versa*, also by milk. Much elaboration is necessary before this discovery becomes of general practical use.

Naturally, our methods of prophylaxis and treatment will not be materially changed. The

peculiar character of the toxic substances produced by the diphtheritic bacillus furnish the strongest indication for the earliest possible local treatment of diphtheria by germicidal agents, and that an equally urgent indication is the destruction of the poisons circulating in the blood, and, in the existing absence of any such antidote, supporting means of treatment should be used, to render the system capable of withstanding the injurious effect of the poison.

DR. WM. OSLER read a paper entitled

THE HEALING OF TUBERCULOSIS.

That pulmonary tuberculosis is curable, is demonstrated clinically by the recovery of patients in whose sputa elastic tissue and bacilli had been found, and anatomically by the existence of lesions in all stages of healing. Caseous areas may be impregnated with lime salts, or the tuberculous masses may be encapsulated by fibrinous tissue, in which case the substance remains quiescent, and the disease is not cured. Perfect healing does not occur after cavities are formed. A cavity may be much reduced in size, but is not often closed. Laennec did much good work in this direction. He recognized the *cicatrices complètes* and the *cicatrices fistuleuses*, and suggested that as tubercle growing in the glands, which we call scrofula, often healed, why should it not do the same in the lungs. In a large number of autopsies healed or quiescent tubercular lesions have been found in the lungs. This was noticed in 1880 by Palmer Howard, who called attention to the great frequency of puckering at the apices of the lungs in elderly persons.

The following is noted of the apices: 1. Thickening of the pleura, usually the posterior surface of the apex, with perhaps subjacent indication of the lung tissue, for the distance of a few millimetres. 2. Puckered cicatrix at the apex, depressing the pleura, which may, or may not be here thickened. On section, there is a fibrous scar much pigmented, the bronchioles in the neighborhood dilated, but no tubercles or cheesy masses. Such structures are extremely common, and may in some cases indicate a healed tubercular lesion. 3. Puckered cicatrices with a cheesy or cretaceous central nodule, and with scattered tubercles in the vicinity. 4. The *cicatrices fistulense* of Laennec, in which one or more cavities have become quiescent, surrounded with fibroid tissue and communicating with the bronchi. At 1,000 autopsies of his over 59 cases, or 5.05 per cent., were found in which persons dying of other diseases presented undoubted tubercular lesions in the lungs. Of the 59 cases, the causes of death were: Cancer of various organs, 12; cirrhosis of the liver, 7; accidents and operations, 85; acute fever, 9; uræmia; 5; diseases of the head and arteries, 5; other affections, 13. The ages of those cases: Under 10 years, 4; from 10 to 20, 2; from 20 to

30, 8; from 30 to 40, 10; from 40 to 50, 14; from 50 to 60, 14; from 60 to 70, 3; above 70, 2. Heitler, of Vienna, found in 16,562 cases in which the deaths were not directly caused by phthisis, there were 780 instances of obsolete tubercle, or 47 per cent. The simple fibroid induration should be excluded. With each decennial period up to the sixtieth year, the number of cases increased. Bollinger found in 27 per cent. in 400 bodies evidences of tubercular lesions in the lungs. Staudacker, in 737 cases, found apex cirrhosis in 202. Massini found evidences of healing in 39 per cent. in 223 bodies examined. Harris, of Manchester, found in 139 cases 54, or 38.84 per cent., in which there were relics of former active tuberculosis. The greater number of these were in the third, fourth and fifth decades. In the Paris Morgue, it is said that 75 per cent. of suicides and those accidentally killed present evidences of old tubercular lesions.

These facts demonstrate, *first*, the widespread prevalence of tuberculosis; and *secondly*, the fact, as shown by the above figures, that at least one-fourth of all infected persons recover spontaneously. In the great majority of cases, the disease was very limited and had made no progress, and could not have given rise to physical signs. But even in cases further advanced, arrest is by no means infrequent, and if not cured, the condition of arrest is consistent with comparatively robust health.

Once infection has occurred, there are three indications: *first*, to place the person in surroundings most favorable for the maintenance of a maximum degree of health; *second*, to take such measures as in a local or general way influence the tuberculous process; and *third*, to alleviate symptoms which are necessarily associated with the disease. The environment is of the first importance. Trudeau's experiments with free and confined rabbits prove this. A patient confined to the house in close, overheated rooms, or in the stuffy, ill-ventilated dwellings of the poor, or even in hospitals, does not stand the chance with the patient in the fresh air and sunshine all day long. The home treatment of consumption is important. Fresh air and sunshine are all-essential. Altitude is a secondary consideration in comparison with these.

Koch's lymph or tuberculin has a very limited use. 1. In a limited number of cases with early local lesions, and not much constitutional disturbance, its use seems beneficial; the cough disappears; the patient gains in weight, and the local signs improve. In none of these, however, after a four months' treatment, can we say there is a cure. 2. In cases with more advanced lesions, particularly with consolidation, the febrile reaction induced is severe, the local condition is aggravated, and the patients lose ground, often with rapidity. 3. In advanced cases, with cavities and

irregular pyrexia, the remedy is most injurious and aggravates every feature of the disease.

Of measures which influence the general condition, apart from hygiene and diet, there are four which have stood the test of experience—cod liver oil, the hypophosphites, arsenic and creosote, all of which act by improving the nutrition, and rendering the tissues more resistant, the soil less suitable for the growth and development of the tubercle bacilli.

In the discussion which followed, DR. WM. H. WELCH said there were two points of importance to be considered: What is our interpretation of the lesions at this apex? What are these fibroid thickenings at the apex? The most frequent lesion found at the apex is a thickening, a slate-colored induration. This contained no caseous nodules, nor calcareous products. Are these healed tuberculosis? If so, then the number of healed cases is large. We cannot say. But even if we leave these out, we have many genuine cases of healed tuberculosis, where there were tubercle bacilli in the sputum. Does it all depend upon the character of the soil on which the bacilli have to grow? There is some doubt on this point. They may vary in their virulence, and some may be of an attenuated character. As high an authority as Koch does not admit this, and this has great weight. Trudeau has reported a case of miliary tuberculosis in which the bacilli were of a very weak character, and Nuttall, in the Johns Hopkins Pathological Laboratory, found a few instances in which the inoculation of genuine pure culture of tubercle bacilli in guinea pigs, usually very susceptible animals, simply caused a localized tuberculosis.

DR. JOSEPH T. SMITH thought the importance of the home treatment could not be too strongly emphasized.

DR. WM. OSLER, in reply to Dr. Branham, said in treating cases with Koch's tuberculin, he used no other therapeutic means. These cases in the hospital now are all doing well. In no case have the bacilli disappeared, but he was glad to say that no case had died under his treatment there, which was probably because all cases treated there had been carefully picked, and only those in the earliest stages had been treated.

DR. JOSEPH T. SMITH then read a paper entitled

THE TREATMENT OF DIPHTHERIA,

in which he discussed the following points: 1. The effect of isolation and disinfection in the spread of the disease. 2. The need of alcohol and iron to influence for good the heart and blood-vessels, and the value of milk as the article of diet. 3. The need of quiet or rest in bed, and the importance of looking upon these as governing our choice of applications to the throat and other forms of medication. 4. The necessity of

calling early upon the surgeon when the disease invades the larynx. 5. The value of as great cleanliness of the pharynx and nares as the condition of the patient will permit.

There are three vexed questions which still await answer: 1. How shall the membrane be dissolved? 2. How shall the bacilli be destroyed at the seat of infection? 3. What is the antidote to the poison? This paper was discussed by Drs. A. K. Bond, W. A. B. Sellman and W. Brunton.

Dr. J. E. MICHAEL read a paper on *Obstetrical Antisepsis*, which was discussed by Drs. Geo. H. Rohé, J. M. Craighill, J. D. Blake, J. G. Wiltshire, A. Friedenwald and W. S. Gardner.

Dr. W. S. GARDNER read a paper entitled *Milk Fever*, which was discussed by Dr. J. E. Michael.

Dr. ROBERT T. WILSON read a paper entitled *Circumscribed Peritoneal Dropsy simulating Ovarian Dropsy*.

Dr. GEO. H. ROHÉ read a paper entitled *The Sanitary Importance of Free Baths*.

Dr. H. NEWELL MARTIN read a paper entitled *Recent Discoveries in the Physiology of Ganglion Cells*.

Dr. J. C. HEMMETER read a paper entitled *The Influence of Digitalis, Ergot and Alcohol on the Blood Fluid*.

Dr. H. N. MARTIN read a paper entitled *The Vaso-Motor Nerves of the Heart*.

Dr. W. T. COUNCILMAN read a paper entitled

THE FORM OF DYSENTERY PRODUCED BY THE AMEBÆ COLL.

Dysentery, as a word, was first used in a clinical sense. It meant tenesmus. It is an inflammation of the large intestine. The pathological lesions are exceedingly numerous and varied. It would be absurd to suppose that all forms of dysentery come from the same cause, just as in pneumonia. The pulse is rapid. The case may last several months. In the anatomical lesions which are produced there is much variation. Some die before ulceration begins, and other cases are not so virulent. The lesions are in the submucous tissue. Clinically the disease is chronic. It begins with a diarrhoea. It is intermittent in character, may last for a month, stop, and then break out again. There is no pain in the earlier stages, but later there is pain; the diarrhoea becomes worse, and there is tenesmus. The stools are mixed with blood. There is usually no fever in the entire course of the disease, emaciation still goes on. The duration may be from three to six months. Towards the last the complexion assumes a dull, earthy-like color. There is nothing distinctive in the stools; they are always fluid, and considerable in amount. When these patients die, the anatomical lesions are exceedingly characteristic. There is entire absence of diphtheritic exudation, which one finds in the

acute cases, and the surface of the bowel shows numerous ulcerations. These ulcers are relatively small, and the surface is mammilated. There is a small loss of substance at the apex of these elevations, and an abscess cavity, and on this a depression is filled with an opaque greyish, gelatinous-looking mass. The entire intestine is much thickened, the muscular coat thickened. Then large ulcers can be found which run into each other, so that we may have long, sinuous passages running through the intestines in various directions, and the membrane becomes undermined, sloughs and falls off. It extends to the mucosa and the muscular coat, and large sloughs are cast off. The microscopic characteristic appearance is evident. The amount of sloughing is often extreme, some as large as the hand.

This is interesting from the complications. The most frequent is the abscess of the liver. He had seen at the Johns Hopkins Hospital eleven cases of this form, of which five died and three are still under treatment. Of these eleven cases, four deaths occurred from liver abscess, and one case of liver abscess is still under treatment. The abscesses of the liver are fully as characteristic as in the intestinal ulceration. The liver abscesses are filled with a gelatinous-looking mass. If they are larger they may have a distinct fibrous form, and look like other forms of abscess.

The next most common complication is abscess of the lung. The formation of abscess of the lung is interesting. In four cases at the hospital, three had abscesses of the lung. The lung abscess comes from the liver abscess. The liver abscess is on the upper surface of the liver. There is an adhesive pleuritis and the lung abscess follows. It is very insidious in its outset, there is always pyrexia, abdominal pain and much sweating. When the lung complication takes place, the appearance of the sputum is characteristic—tough, of dingy cherry-red color, as in acute pneumonia, so that the spit-cup can be turned up without the sputum running out. The sputum also contains small masses of necrotic tissue, lung tissue. The cause of the disease has long been suspected. Davaine, in 1853, described the cercomas in the stools. Then Lander, in Prague, found small amebæ in the stools of a child which had died of dysentery, also in cholera. Cholera patients in India by Cunningham and Lewis. Lersch, of St. Petersburg, was the first to describe this as we now know it. It is an amebæ *Trichostema* of an inch in length. It is either round or is undergoing movements. The outer part is a homogeneous mass, and the inner part is filled with granular matter. The movements are active, and its large size makes it easy to study under a low-power microscope. It may be seen to change its form and shape under the microscope. It puts out its pseudopodia and draws them in again. It is found in the stools, in the abscess of the liver and

lung. We find in it things which the organism has taken up for food, as, for example, red blood-corpuscles. The organism may be seen in the microphotographs which are passed around. He thought this form of disease was not so uncommon as many thought. He had tried to find the geographical range of the disease. Woodward also had written largely on dysentery, had recorded 693 deaths from intestinal affection.

DR. WM. OSLER thought the form very peculiar and destructive. He referred to one case he had seen in consultation.

DR. A. FRIEDENWALD thought that Woodward's cases died too soon to have the abscess occur. They develop late in the disease.

DR. J. C. HEMMETER asked if the amebæ had been clarified, and if they had been artificially cultivated.

DR. W. T. COUNCILMAN said that Cunningham, in 1879, had cultivated them, not in pure culture, and had possibly found these forms. He used a strong solution of cow dung. Another investigator had obtained a pure culture and produced the disease in cats. Most animals are immune from injection of the stools. He regarded the amebæ as the undoubted cause of the disease.

DR. HIRAM WOODS read a paper entitled

BLINDNESS IN THE UNITED STATES,

in which he quoted numerous statistics to show increase in blindness, particularly among the poor, principally from ophthalmia neonatorum. He recommended the more widespread caution to the poor that could be distributed throughout the city, in the hospitals, dispensaries and station-houses. At his suggestion, the President appointed Drs. Hiram Woods, A. Friedenwald, J. E. Michael and G. H. Rohé, a committee of four to attend to this.

DR. FRIEDENWALD thought it was the best paper he had ever heard of on the subject. The difficulty is not want of knowledge, but carelessness, which causes blindness in the newborn.

DR. GEO. H. ROHÉ referred to the absence of ophthalmia neonatorum at the Maryland Maternity, in a large number of births.

DR. R. L. RANDOLPH thought that emphasis should be laid especially on the quantity of the silver nitrate used. Too strong a solution acts as a caustic. In a child, the secretion of tears is scant, and there is less chance of an excess of the agent being neutralized. More than one drop should not be used.

DR. W. T. CATHELL then read a paper on *Enlarged Tonsils and their Detrimental Effect on Health and Development*.

DR. J. W. HUMERICHOUSE, of Hagerstown, read a paper entitled *Four Cases of Diphtheritic Laryngitis* in which intubation was performed with one recovery, and one case of recovery without operation.

The following volunteer papers were read:

"The Physical Training of the Feeble-minded," by Dr. Samuel J. Fort.

"The Revival in Physical Training and Hygiene," by Dr. Edwin M. Shaeffer.

"A Second Series of 100 Cases of Labor at the Maryland Maternity," by Drs. Geo. H. Rohé and Samuel H. Allen.

"Two Cases of Bilateral Homonymous Hemianopsia," by Dr. Geo. J. Preston.

"Acute Miliary Tuberculosis treated with Tuberculin," by Dr. Jno. C. Hemmeter.

"Certain Pathological Effects of Aneurism," by Dr. N. G. Kierle.

"Intra-uterine Diseases of the Eye," by Dr. J. J. Chisolm.

"The Function of the Omentum," by Dr. Howard A. Kelly.

"Two Obstetric Cases," by Dr. W. Brinton.

"A Case of Cancer of the Bladder" (with specimen), by Dr. Jas. Brown.

"Supra-vaginal Hysterectomy," by Dr. Thos. Opie.

The following were elected for the ensuing year:

President—Dr. W. H. Welch.

Vice-Presidents—Drs. J. W. Humerichouse and David Street.

Secretaries—Drs. G. L. Taneyhill, R. T. Wilson, J. T. Smith and Wm. B. Canfield.

Treasurer—Dr. W. F. A. Kemp.

St. Louis Medical Society.

Stated Meeting Saturday, January 31, 1891.

THE VICE-PRESIDENT, DR. J. C. MULHALL,
IN THE CHAIR.

Abstracted from THE JOURNAL.

DR. H. C. DALTON presented the following specimens with sketches of the corresponding cases:

DIAPHRAGMATIC HERNIA, TRAUMATIC.

The case was a man, æt. 26, who received a stab wound two and one-half years before, in the left thorax at the seventh intercostal space and two inches posterior to mammary line. Patient entered hospital at the time of this injury, and was discharged apparently cured in a few days. January 22, 1891, he was readmitted to hospital, suffering greatly. Pulse 90, temperature 103. Five days before admission he had severe pain in umbilical region, and bowels had not moved, despite efforts to that end. Vomited first day of attack, not since. Abdomen swollen and hard. Pain constant and increased on pressure. Consulting surgeons advised laparotomy, though a clear diagnosis was not made previous to the operation.

Abdomen was opened and a general peritonitis found. Upon search a diaphragmatic opening

was discovered through which all the omentum and twelve or fifteen inches of the colon had passed into the left thoracic cavity. Efforts to withdraw the mass were fruitless, and a slight incision of the diaphragm was made, when reduction at once occurred. Patient was very weak after the operation, and died in four hours. Undoubtedly the diaphragm was cut through at the time of the stab injury over two years since, leaving a weakened cicatrix which eventually gave way in front of abdominal pressure.

The specimen was presented showing the pathological condition.

In commenting upon the case Dr. Dalton said the literature upon the subject of diaphragmatic hernia was very meagre, surgical authorities referring to it but briefly.

LACERATION OF MESENTERY; RESECTION OF ILEUM.

Patient aged 48. Eleven and one-half hours before admission to hospital patient fell from a wagon, and while on the ground a companion jumped from the wagon landing on patient's abdomen with both feet. Great pain, abdomen swollen and tender. T. 103, P. 132. Laparotomy. Two quarts of blood were washed out of the peritoneal cavity. Mesentery of ileum was found torn entirely through for about a foot parallel to and about two inches from the gut. Intestine was dark, and showed commencing gangrene. One foot of ileum was resected by V-shaped incision and circular enterorrhaphy. Patient died ten hours after operation.

Uterine Fibroid.—Delivered from vagina after strong expulsive efforts of uterus and adjunct muscles. Attached to fundus uteri by small pedicle, which was broken and mass removed with but little hæmorrhage.

TREPHINING FOR SEVERE HEADACHE.

DR. T. F. PREWITT presented a case in which not only was the pain relieved, but a restoration of the function of the eye was had after blindness had continued for nine years.

DR. WILLIAMS inquired what were the ophthalmoscopic appearances of the optic disc?

DR. BREMER replied that the eye was absolutely normal so far as could be seen.

DR. A. B. SHAW thought the result rather tended to confuse the location of the centre of sight, the opening in this case being much above either the annular gyrus or cuneus, high up over the first occipital convolutions in the region of the posterior fontanelle. The speaker felt that in the light of our present returns regarding cerebral surgery a greater boldness was permissible.

DR. DICKINSON said that a few sources of the origin of the optic nerve are distinct and demonstrated, but the entire number is infinite. The entire cerebral cortex doubtless contributes.

THE PRESIDENT spoke at considerable length and with much clearness about the case, having had a knowledge of the peculiarities previous to the operation. He said the question of hysteria could be eliminated entirely, and that the outcome of the operation, as to the restoration of sight to the patient, was indeed a wonderful achievement. The operation was done for the relief of the intense pain, and without a thought of any effect upon the vision. The case should be carefully watched, and the permanency of the results noted.

DOMESTIC CORRESPONDENCE.

Ovariectomy as a Prophylaxis and Cure for Insanity.

To the Editor.—I wrote an article on this subject in March of this year. I further report concerning the same case.

Miss Ada N., age 28, had been insane for 13 years, when on February 4, 1891, I made my first ovariectomy upon her, with the result as shown in my article of March, 1891. The young lady continues to improve mentally and physically. Hers was a case of hysterical insanity, although the case had been for 13 years pronounced a case of dementia. As stated in my first article she had had scarlet fever at 13 years of age; just at the time when the ovaria were developing into active maturity, and were consequently checked and diseased. She complained of ovarian pain for years, increased at each menstrual epoch. Now here is one of those cases wherein the sympathetic nervous system was at fault and not, as was frequently diagnosed, "mental disease." This case illustrates beautifully the reflex effect of disease of the generative organs.

The patient is now undergoing an "artificial change of life."

Her present condition and symptoms are precisely those of the menopause. She has not uttered one irrational word since the removal of the ovaria. Her former pain and symptoms have entirely subsided. She talks freely and rationally, and is daily gaining strength. I should like to hear from some of the readers of THE JOURNAL upon this case.

Diagnosis.—I believe too much care cannot be exercised in discriminating between real and pseudo-insanity. In this case of Miss N., there was abundant evidence in favor of the theory that scarlet fever was the cause of her insanity, as having produced structural lesion in the brain; but at the same time there appeared positive evidence of ovarian irritation which had been present from the very beginning of menstruation; yet the fact appears to have been lost sight of by every medical man under whose eye the girl had passed. I am compelled to say, and that without egotism, I trust, that specialists are too liable to lose sight of general symptoms and signs and form or base their opinions upon points or signs peculiar only to their respective specialities, thereby being not infrequently misled from a lack of power in generalizing such cases.

I shall report the future condition of this lady from time to time and acquaint the readers of this JOURNAL with her future state of mental and physical health.

Case 2.—Miss J. W., Elizabeth, Ill., age 28 years. Fair health; medium height; blonde. Has been in poor health since menstruation made its appearance.

I was called to Elizabeth, Ill., on March 1st, of this year, to examine and pass my opinion upon this lady's case. I found a fine looking young lady confined in

an iron cage. Miss W. had been confined for something over two years; she had not a stitch of clothing on her person, nor had she been able to keep any clothing on her for two years. She would tear every thing in the way of cloth to shreds; even carpets they could not keep tacked to the floor. She had a mania for tearing and destroying things that were placed in her cage; therefore the only article in the shape of cloth that she could not mutilate was the heaviest sailing cloth, and of which cloth her mattress (that being the only article movable in her cage) was made, also one very tough sheep skin which constituted her sole bed covering. In this condition I found Miss W. Her language was continually abusive, profane and obscene. She appeared to possess a grudge against all men. The presence of a man would always excite obscene and profane language. She was constantly, during the day time, climbing to the ceiling of her cage and would drop herself down on her hip to the floor, seemingly endeavoring to kill herself or hurt herself in order to get relief from her pain. She would turn complete summersaults forward or backward; she would run up and down her cage, scream, swear and tear her hair and in every way possible abuse her body. When quiet, she would lie down, doubled up like a four legged animal; showing conclusively that a relaxation of the abdominal muscles was a relief to her pain. She would go for days without a bite to eat. She would defecate on the floor most of the time; having only straw on the floor it was periodically removed, and this could be done only by the help of several attendants. In this terrible plight I first saw Miss W.

Diagnosis.—With the assistance of three strong men I entered her cage to examine her, she being thrown down and her face covered with an ordinary base ball mask, and hands and feet bound down and held by the attendants. I proceeded to examine the case. I found the heart very much hypertrophied, from over exercise. Lungs sound. Bowels tender and mesenteric glands very much enlarged; both the ovaries were large, tender and very much displaced downward. Upon touching the finger against the clitoris and vagina, she began to work up and down as in the act of intercourse and began a volley of obscene language, which she kept up during the digital examination. I could come to no other conclusion than that this was a case of ovarian disease with that nymphomaniac tendency which were in all probability the primary causes of her insanity.

The history of the case from the very beginning of menstruation tended to show that there was ovarian disease, but she had been simply regarded as a little cranky from girlhood up to 23 years old, when she had a low affair with a young doctor who they claim had probably insulted her, when all at once she became demented and was submitted to Elgin, Ill., asylum, where she remained two years.

Treatment.—Having diagnosed this case of ovarian trouble, I suggested an immediate operation of removing the offending organs. Accordingly with my first assistant I started from Racine, March 1st, and proceeded to Elizabeth, Ill., where on March 2nd, I performed the operation of ovariectomy.

I found, as predicted, both ovaries, with their tubes, badly diseased, being in a fibro-cystic condition; both tubes were four times the usual size, congested and in a state of pyosalpinx. There was downward dislocation of both organs with extensive adhesions. The peritoneum in the region of the organs was much thickened and congested, presenting a yellowish pink color, showing conclusively a congestion of long duration; the effect of the operation wore away in a few hours, when she emerged from it feeling weak and tired. She presented a different facial aspect within forty-eight hours; that peculiar idiotic terrible set expression had gone. She talked quite rationally most of the time for ten days, calling for the bed pan and otherwise showing a great change. She talked of many things which had happened years ago.

She recognized all her relatives and seemed quite rational. She would ask pleasantly for food and drink, and express her thanks when anything was done for her comfort. Her family generally expressed their feeling that reason had indeed resumed her sway. Her former obscene language and profanity had entirely been forgotten. Her actions were quite right. She did not need to be tied. After the fifteenth day she began to tear a little, although she used no bad language nor talked insanely. After twenty-one days, which time was her usual time for menstruation, she appeared to grow more normal mentally, but nothing of her former trouble has yet shown itself. I should like to hear the opinion of the profession upon this case.

I shall write again upon this case and give full particulars. I do not attempt here to offer anything original or new in the treatment of insanity, nor revise the long since tried treatment of ovariectomy for insanity, but simply to show what may be accomplished in certain cases.

I am a young and inexperienced surgeon and am open to any criticism my professional brethren may see fit to offer. This is my fourth ovariectomy for insanity. The third case I shall endeavor to report next month, it being one of marked diagnostic interest.

DR. ROBERT A. KITTO.

Idiosyncrasy Towards Eggs.

To the Editor.—I desire to place on record the following: A lady 27 years of age, has since a child never been able to eat an egg without suffering an attack of cholera morbus to all appearances. The same condition occurs when she eats them in any form, as cake, etc., or any method of preparing them. The lady is in all other respects normal and in good health and development.

J. CH. DODDS, M.D.

Denver, Col.

NECROLOGY.

I. L. Drake, M.D.

At the regular meeting of the Lebanon Medical Society, held in Lebanon, Ohio, May 26, 1891, the following resolutions were unanimously adopted:

WHEREAS, It has pleased Almighty God to remove from his earthly sphere our worthy professional associate, Dr. I. L. Drake, of Lebanon, Ohio, one of the oldest, ablest, most devoted and useful members of this society; we, his surviving brothers, deeply conscious of the loss we have sustained, wish formally to record our high appreciation of his character, his work and his worth: be it, therefore,

Resolved, That we hereby express our sincere grief for the sadly sudden death of our friend: an elegant, cultivated, affable gentleman; active, earnest, patient in his search after truth; constant, courageous and firm in maintaining the right as he saw it; an honest christian man. In obedience to the Almighty power that rules the destinies of men, that can build up or cast down, that can give or take away, we bow in humble submission about the loss of our departed fellow member and professional brother.

Resolved, That we most heartily tender to Dr. Drake's bereaved family and relatives this expression of our profound sympathy, and the acknowledgement, that in his

death we lose a true and cherished friend and co-laborer; and be it further

Resolved, That a copy of these resolutions be sent to the family of the deceased, and that they be furnished to the papers of Lebanon, the *Cincinnati-Lancet Clinic*, and to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

B. H. Blair, R. S. Michel, Jno. Wright, E. J. Tichenor, H. J. Death, S. S. Seville.

DR. KARL BRAUN VON FERNWALD, the eminent professor and author, of the Vienna University, died during the last week in March. He was appointed to the chair of midwifery and became the head of the famous gynecological Klinik over thirty years ago. His writings have been among the most sought after of those devoted to his chosen subjects and he enjoyed a pre-eminent popularity among the Viennese students. He was in the seventieth year of his age and the fortieth year of obstetric teaching, at the time his death.

DR. ALFRED HOSMER, who died May 14, at Watertown, Mass., was one of the ex-presidents of the Massachusetts State Medical Society, and formerly a member of the State Board of Health and Charity. He was one of the founders of the Medico-Legal Society and a medical examiner for fourteen years. He was also, for many years, the post-surgeon of the United States Arsenal at Watertown. He was a frequent contributor to the medical journals on obstetrical and medical-legal subjects. He was in his sixtieth year.

DR. OTIS STANTON, of Washington, D. C., died April 9, in his fifty-third year. He was a native of Strafford, New Hampshire, having been born there October 22, 1837. He obtained his medical education at the Bowdoin College, graduating in the class of 1862. In that same year he became acting assistant surgeon and served in and around Washington until the latter part of 1865. He then took up practice at that city, giving special attention to gynecology. He was a member of the board of directors of the Columbia Hospital for Women and Lying-in Asylum. He was a corresponding member of the Gynecological Society of Boston. His death took place after a brief illness by pneumonia superinduced by epidemic influenza.

MISCELLANY.

RESIGNATION AND APPOINTMENT.—Dr. J. B. Hamilton, Surgeon-General of the United States Marine-Hospital Service, has resigned in order to enable him to accept of the Professorship of Principles of Surgery in Rush Medical College. Dr. Walter Wyman succeeds Dr. Hamilton in the National Service.

Dr. Hamilton's marked success as a sanitarian, and ability to grasp at once and meet the necessities of any

situation of threatened danger from epidemic disease, are familiar to every reader of current history.

Many regrets will be expressed at his retirement from a position where his services have been of inestimable value to the entire country, while his appointment as one of the faculty of Rush cannot but add to the already prosperous condition of this well-known school of medicine.

Dr. Walter Wyman is the legitimate successor of Dr. Hamilton, and will no doubt fully sustain the enviable reputation of his predecessor.

WASHINGTON STATE MEDICAL SOCIETY.—The second annual meeting of the Washington State Medical Society, held in Seattle, May 6 to 8, was largely attended. Papers on the following subjects were read and ordered printed with the proceedings of the meeting:

Annual Address, by C. K. Merriam, Spokane.
Anatomy, Dr. E. E. Heg, North Yakima.
Physiology, Dr. H. P. Tuttle.
General Surgery, Dr. N. Fred. Essig, Spokane.
Abdominal Surgery, Dr. E. L. Smith, Seattle.
Surgery of the Brain, Dr. J. B. Wintermuth, Tacoma.
Genito-Urinary Surgery, Dr. C. H. Willison, Port Townsend.

Report on Obstetrics and Gynecology, by Dr. J. J. McKone, Tacoma.

"Do Maternal Impressions Affect the Fœtus in Utero?" by Dr. T. V. Goodspeed, Seattle.

"Treatment of the Insane," Dr. J. W. Waughop, Steilacoom.

"Analgesia of the Insane," Dr. W. J. Redpath, Steilacoom.

"On the Existence of an Intellectual Center," Dr. G. S. Armstrong, Olympia.

"Increased Reflexes and Allied Phenomena," Dr. C. W. Sharples, Seattle.

"Importance of Free Nasal Respiration," Dr. A. B. Kibbe, Seattle.

The following officers were elected for the ensuing year:

President, H. C. Willison, Port Townsend.
First Vice-President, G. W. Libby, Spokane.
Second Vice-President, H. P. Tuttle, Tacoma.
Secretary, Elmer E. Heg, North Yakima.
Treasurer, James B. Eagleston, Seattle.

Next meeting will be held in North Yakima, Washington, beginning the second Wednesday in May, 1892, and continue for three days. ELMER E. HEG, Sec'y.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from May 23, 1891, to May 23, 1892.

Capt. Paul B. Brown, Asst. Surgeon, U. S. A., is granted leave of absence for one month, with permission to apply for an extension of one month. Par. 4, S. O. 59, Dept. of the Missouri, St. Louis, May 26, 1891.

Capt. Marlborough C. Weth, Asst. Surgeon, granted leave of absence for three months, on surgeon's certificate of disability. By direction of the Secretary of War. Par. 6, S. O. 119, A. G. O., Washington, May 25, 1891.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending May 27, 1891.

Surgeon John Vansant, granted leave of absence for seven days. May 22, 1891.

Surgeon Fairfax Irwin, granted leave of absence for twenty-one days. May 11, 1891.

Asst. Surgeon G. M. Gutiérrez, relieved from special duty at New York City, ordered to San Francisco, Cal. May 11, 1891.

Asst. Surgeon J. E. Gienewick, relieved from duty at New York Marine-Hospital, ordered to Gulf Quarantine. May 22, 1891.

Asst. Surgeon G. B. Young, granted leave of absence for thirty days. May 11, 1891.

PROMOTIONS.

P. A. Surgeon T. B. Perry, commissioned as such by the President. May 23, 1891.

P. A. Surgeon R. M. Woodward, commissioned as such by the President. May 23, 1891.

THE PREVALENCE OF ALBUMINURIA IN PERSONS APPARENTLY HEALTHY.

*Read in the Section of Practice of Medicine and Physiology at the
Forty-second Annual Meeting of the American Medical Association,
held at Washington, D. C., May 15, 1891.*

BY WILLIAM B. DAVIS, A.M., M.D.,
OF CINCINNATI.

I read a paper before the American Medical Association at its Forty-first Annual Meeting, held in Nashville, Tenn., May 20th, 1890, on the subject of "Functional Albuminuria, or Albuminuria in Persons Apparently Healthy," in which I reported a case which had been under my observation for five years. On March 5th of this year, 1891, I made a careful urinalysis of this person's twenty-four-hours' urine, examining separately each specimen as voided, and then mixing them together and again examining a sample of the whole quantity. The tests used were cold nitric acid,—contact method,—and boiling, then adding a drop or two of nitric acid and again boiling. The following are the results, viz.:

	COLOR	RE- ACTION	SPEC. GRAV.	ALBUMEN
Urine passed at 7 A.M.	Dark straw	Acid	1.020	No albumen.
" " 11 A.M.	Straw		1.020	Faint trace
" " 3:15 P.M.			1.025	Faint trace.
" " 7 P.M.			1.020	Faint trace.
" " 9 P.M.	Dark Straw		1.025	Small quantity
" " 10 P.M.	Straw		1.020	A trace

Whole amount of twenty-four hours' urine, 32 ounces; reaction, acid; color, dark straw; specific gravity, 1.025; albumen, a faint trace. Without the addition of the 9 P.M. urine, albumen was not discoverable. The 9 P.M. urine was the only sample which gave any deposit of sediment after standing twenty-four hours. A microscopical examination of this sediment resulted as follows, viz.:

1. *Casts*. Only an occasional hyaline cast.
 2. *Crystals*. Calcium oxalate crystals present in great numbers.
 3. *Epithelium*. Pavement and small round bladder epithelial cells present in small numbers.
- Another examination of his urine was made on March 21st, 1891, with about the same results, except that less reaction was obtained than on any former examination. The night urine con-

tained no albumen, and the urine passed two hours after his mid-day lunch contained the most albumen; after standing twenty-four hours it constituted one-twentieth of the urine in the test tube. The specific gravity of the twenty-four hours' urine was 1.028, reaction acid, color dark straw. During the six years he has been under my observation his twenty-four hours' urine has never exceeded 40 ounces in quantity and the specific gravity has never been lower than 1.020. His early morning urine has never contained albumen, although it has invariably been present in small quantity at some hour later in the day. He has always been, and still is in the best of health seemingly. He has not had a day's illness in ten years. He has not had rheumatism, gout, lead poisoning, syphilis, nephritis, dyspepsia or dropsy. No member of his family has had any of the above diseases or any history of Bright's disease. In his case there is no increase of vascular tension, no cardiac hypertrophy, palpitation or dyspnea, and no retinal symptoms. He is 36 years of age, temperate in all his habits, happily married, prosperous in his business, resides in a suburban home where he spends his time after business hours. This case of albuminuria, which I present to you, is not a hypothetical,—a supposititious case, such as our learned brethren of the bar are accustomed to fire at the unfortunate disciples of Esculapius. When they get them at short range upon the witness stand, but he is a living being, like ourselves, who has been under my observation for the past six years. His case is not an exceptional one, but a typical one, and has been observed, studied and recorded the world over. Pavy designates this condition as "cyclical albuminuria." Senator, who fully endorses Pavy's observations, prefers the term "paroxysmal," while other equally eminent observers believe that "intermittent" is the best name for it. I shall not consume any time in the discussion of the merits of these particular names, but shall speak of this form of albuminuria, and the other forms which may occur in persons apparently healthy, as "functional albuminuria."

Now what is the clinical significance of the albuminuria in a case like this? If this man had not made application for life insurance six years

ago, no one, up to this date, would have known, or even suspected that anything was the matter with him. For all practical purposes he was and is a perfect specimen of manhood. During these six years he has become the father of three healthy children, has amassed a fortune in his business, is a public spirited citizen, and prominent in all benevolent and church work.

During the past fifty years albuminuria has been regarded as the one infallible symptom—if not synonym—of Bright's disease. As a consequence, the patient in whose urine albumen was found, was regarded as a doomed man, as Bright's disease was believed to be necessarily fatal. After a time, however, it was found that albuminuria was frequently present in other diseases, as for example, pregnancy, the puerperal state, zymotic and other febrile diseases, lead poisoning, etc. These discoveries modified its significance somewhat, but did not materially reduce the gravity of its presence in other cases. Then, such a veteran authority as Prof. Geo. Johnson asserted that albumen, to a large amount, may be constantly present in the urine of men, women and children who are apparently in good health, and he even went so far as to say that "it has been proven by abundant experience that the mere fact of albumen, even in large amount, filtering through the walls of the malpighian capillaries does not seriously, if at all, interfere with the proper excretory function of the convoluted tubes."

Then, Finlayson, Mahomed, Fraser, and other eminent authors, demonstrated that structural disease of the kidneys, or Bright's disease may actually be existant without albuminuria, and Prof. Fraser informs the profession that "albumen is only one symptom" and that all forms of Bright's disease are accompanied by other symptoms.

Then, Prof. Grainger Stewart makes the remarkable statement "that cases of Bright's disease do not account for one-half of the cases of albuminuria met with in practice," and Dr. Saunders, in his recent work on Bright's disease, makes this astounding utterance: "The practical outcome of the study of the incidence of albuminuria in the sick and the healthy should be to extinguish altogether the pernicious doctrine that albuminuria means organic disease of the kidneys, a doctrine less harmful than the equally fallacious one that organic disease of the kidneys is a rapidly fatal disease." And then the *British Medical Journal*, in a leading editorial makes the broad announcement that "albuminous urine is no longer the equivalent expression for Bright's disease," and says "the attention of the profession, during the last few years, has been called to the fact, by repeated observations, that al-

bumen may be found in the urine of persons who do not exhibit any of the general symptoms of Bright's disease, nor even any evidence of any deterioration of health." Finally, Prof. Moxon, after relating the various causes which will produce temporary albuminuria, says: "Albuminuria becomes in relation to disorders of the renal system what neuralgia is to disorders of the nervous system, or what dyspnea is in disorders of the respiratory system—a name of a symptom—which is on the very outskirts of an intimate knowledge of any case, and thus albuminuria, as Dr. Bright knew it, becomes by-gone and historic."

These utterances from such authoritative sources are sufficient to warrant the opinion that the significance of albuminuria, as first announced, was overestimated; nevertheless, its grave significance is so thoroughly ingrained in the profession that we can scarcely admit of any other condition than a pathological one as being compatible with its presence.

Prevalence of Albuminuria.—Until a few years since, it would have been considered rank heresy for any person to have suggested that albuminuria was compatible with any other condition than that of organic renal disease, and a physician would have been looked upon as somewhat unbalanced in his mind who would have asserted that albuminuria would occasionally be found in persons apparently healthy, but now the medical press, in both Europe and America, claim that it has been found in a large percentage of people otherwise healthy; and this claim has been supported by so many eminent physicians the world over, that there seems to be no doubt of its correctness.

In our country Shepherd found albumen in the urine of 2 per cent. of 35,471 persons examined. Washburn, of Milwaukee, found it in 5.91 of 338 examinations of healthy persons for Life Assurance. Munn found it in 11 per cent. of a large number of individuals "who considered themselves perfectly healthy." Edes states that the presence of albumen in minute traces, or something that gives a similar reaction with the most delicate re-agents, is much more common than its absence, and the amount detectable by heat and nitric acid may be approximately stated as from 10 to 20 per cent. of persons examined.

In Great Britain and in Europe larger percentages have been found. Grainger Stewart, in a report to the Royal Society of Edinburgh, stated that he found albumen present in 31 per cent. of 407 urines from healthy individuals and he concluded his report by saying "that albuminuria is much more common among presumably healthy people than was formerly supposed, tests having demonstrated its presence in nearly one third of the population."

Dr. Turner, Medical Officer of Essex County

Dr. Purdy, of Chicago, in 1886, collected from Guy's and other hospital reports, 250 cases of chronic Bright's disease in which albumen was present in only 6 cases, leaving 144 cases, nearly 71 per cent. in which albumen was absent.

Insane Asylum, England, found albumen in the urine of 40.2 per cent. of 200 male inmates, and in another Insane Asylum, Kleudgen found albumen in 43 per cent. of the healthy nurses. Stirling found it in 44 per cent. of 461 healthy adults examined by him; Capitan found it in 45 per cent. and in children 80 per cent.; De la Celle-Chateauberg says it may be found at times in the urine of 75 per cent. to 100 per cent. of healthy persons, both young adults and children; Posner asserts that he has proven the existence of albumen in all normal urine, and his experiments have received the stamp of approval from such men as Senator, Duden, Leube and V. Noorden. Washburn, of Milwaukee, in *The Medical News* April 5th, 1890, says that in order to verify the claim of Posner, he tested with picric acid by the contact method, and also with the phenic acetic test, and with a solution of citric acid of a specific gravity of 1.008 by the same method, samples of urine from fifty persons in perfect health, all living in good sanitary surroundings, and "in every instance, at the line of contact of the two fluids, the characteristic cloud appeared with more or less distinctness indicating the presence of an albuminoid."

Prof. Senator, of Berlin, in his recent work entitled "Albuminuria in its Physiological and Clinical Relations" Berlin, 1890, says "the more complete methods of investigation and the application of delicate tests have had as a result the discovery that albumen is frequently found in the urine of men who exhibit neither objective nor subjective symptoms of disturbances of health, and who after a long continued observation, appear to be perfectly healthy." From the reports of a number of the best authors, he says: "we are warranted in believing that albumen is found in the urine without any other discoverable pathological changes, in a surprising number of cases. Forty-one out of every one hundred healthy, strong men, especially soldiers, under ordinary circumstances have albuminuria." Senator holds that we may regard the appearance of albumen in the urine of healthy men as the "Physiological albuminuria, just as there exists a physiological glycosuria, oxaluria and indigouria."

Sir Wm. Roberts says it has been both affirmed and denied, on high authority, that traces of serum-albumen exist in normal urine. "I have satisfied myself" he says, "that concentrated urines from persons in undoubted health are comparatively rarely free from traces of albumen, detectable by direct testing. In ordinary processes of testing urine, these traces are naturally overlooked, but they certainly exist very frequently, and their existence shows how nearly on the verge of a sensible albuminuria healthy people are."

The Proteids of the Urine.—It is somewhat remarkable that the recorded observations in our country show a very low percentage of albumi-

nuria in persons apparently healthy when compared with those of our British and Continental cousins. I asked Dr. Victor C. Vaughan, Prof. of Chemistry in the University of Michigan, why it was that physicians in Great Britain and Europe, men of undoubted ability and world wide fame, were finding albumen in the urine of 20, 30, 50, 70 and 100 per cent. of healthy persons examined by them, when the highest per cent. reported in our country was but from 10 to 20 per cent? In reply to my inquiry he wrote: "I will agree to the statement that *proteids* are frequently found in the urine of the healthy, or those who so far as they themselves or any one else may know, are healthy," and he called my attention to an article on "The Proteids of the Urine, with a comparison of the Tests for Albumen" by F. G. Novy, M.S., Instructor in Physiological Chemistry, University of Mich., *Medical News*, Vol. 53, 1888, and said "you will see from this article to which I have referred you, that with some of the proposed tests you can find albumen in the urine of almost any one." In this article Mr. Novy calls attention to the fact that serum-albumen is the only proteid which the average physician expects to find in the urine. Whereas, globulin, hemi-albumose (hence Jones albumen) and peptone, are also frequently present. In the ordinary methods for testing for albumen, all of these proteids but peptone may be readily mistaken one for another, and, indeed, he says, "this has been rather the rule than the exception." Serum-albumen is generally considered to be indicative of structural disease of the kidneys, but the other proteids have no such grave significance, nevertheless serum albumen is usually accompanied by larger or smaller quantities of globulin, and in some instances, even peptones may be present. "Our ordinary tests for serum-albumen are also responded to by globulin and, hence, when applied to an albuminous urine, they indicate, as a rule, a greater amount of serum albumen, than that actually present."

Globulin usually accompanies serum-albumen and may be present in almost all varieties of albuminuria, though in variable quantity. According to Haumaisten, it constitutes from 8.13 to 60.24 per cent. of the total proteids in albuminous urine. The more recent investigations of Maguire indicate that globulin can exist in the urine by itself, even without serum-albumen being present, and he reports three cases of cyclic or functional albuminuria, and one of puerperal albuminuria, where he found the proteid of the urine to consist solely of globulin. Novy also mentions one case of functional albuminuria which came under his observation where globulin alone was found in the urine. These reports accord with the statement I made in my paper on "Functional Albuminuria" read before the American Medical Association May 22d, 1890, viz.:

"The present line of investigation is pointing strongly toward globulin as the form of albumen which is likely to be found in the various forms of functional albuminuria when chemistry will furnish us with simpler methods and more reliable reagents for its discovery."

ELECTRICITY AS A THERAPEUTIC AGENT. WHAT IS NEEDED TO DETERMINE ITS MERITS?

Read in the Section of Practice of Medicine and Physiology, at the Forty-seventh Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1911.

BY W. J. HERDMAN, M.D.,

OF ANN ARBOR, MICH.

There are few subjects toward which the mind of the medical practitioner is more in need of proper adjustment than that of the use of electricity as a therapeutic agent. It is now more than a century since a professor of anatomy in the University of Bologna announced to the profession—that is daily puzzling its brains over the various ills that flesh is heir to—that he had discovered, in the association of dissimilar metals with the legs of decapitated frogs, a force was generated capable of acting as a substitute for nerve impulse in causing muscular contraction.

Electro-physiological inquiry received a new impulse from this discovery of the effects of a continuous or galvanic current on living tissue, and from that time on there has been an unceasing activity displayed by many of the best minds in the profession, in adding to our knowledge of the power of electricity in modifying and controlling the vital processes going on in animal structure, until medical and scientific literature is burdened with the rich fruit of their researches.

Many of the discoveries in electro-physiology suggest valuable additions to our therapeutics, and while there have not been wanting examples of able men in the profession, like Remak, Duchenne, von Zeimssen, Erb and De Watteville, who have used their best energies to gain for electro-therapeutics the recognition which its importance deserves, its power as a curative agent is as yet but imperfectly understood by the vast majority of physicians. The reason for this is readily explained. The work of the physiologist, though indispensable as antecedent to rational therapeutics, is often in too crude a state to be readily made available by the busy practitioner. A hiatus exists between the discoveries of pure science and their practical application to the requirements of everyday life. Men are rare who have either the time, the opportunity or the ability to acquire such experience in both fields of research as to adapt the discoveries of the one to the needs of the other. Electric physics, physiology and pathology, each are so comprehensible in their scope

that, with the best facilities, a lifetime is spent in acquiring a knowledge of what is known of each. It is no wonder, then, that, during the past century, in which so much has been revealed concerning the mysterious working, both on the organic and inorganic world, of that strange force we call electricity, so little practical use has been made of it by the physician, and that it has, in common with many other discoveries, in the twilight of their early dawn, been seized upon by the impostor and charlatan as suitable instruments with which to prey upon the minds and pockets of a credulous and expectant world; and when, in addition to this, we recall the fact that there has existed among those who have attempted to direct our minds toward the therapeutical application of electricity, the greatest diversity of opinion as to the form of currents that should be used, and the methods for applying them, and that no attempt has been made at uniformity even in the instruments employed for this purpose, it is not surprising that electricity as a therapeutic agent has been looked upon as of rather doubtful efficiency by the majority of physicians. But, fortunately, while these causes have operated to bring electricity into disrepute in the minds of conscientious practitioners of medicine, the rapid strides it has made in other fields of usefulness have raised it in importance and esteem, so that its power and efficiency must be everywhere recognized by the man, be he medical or lay, whose daily life is so dependent on its labor. It now requires but little argument to convince any man that electricity may probably effect some change in the disordered state of his bodily economy, who, every hour of the day, is depending upon this selfsame force to aid him in the minutest details of his daily life. Nor does the physician now entertain that same contempt which once he might have done for an agency which, in these latter days, lights up his house, washes his linen, stitches his clothes, prints his newspapers, cooks his meals, transports him to his office, and brings him into communication with his patients, far or near, while sitting at his desk. So insidiously have the commercial uses of electricity crept in upon us, and so indispensable have they become already to our comfort, that were we, as a people, thrown back on the resources of even a decade ago, we would feel somewhat the same uneasiness and discomfort that Rip Van Winkle expressed on waking from his long sleep. While the profession at large has given but little or no attention to the therapeutic uses of electricity, there has been a skirmish line in advance of the main body, that has not been idle, and along this line there have not been wanting bold and self-reliant spirits who, with the directness of aim and the clearness of observation of the sharpshooter, and with a genius for experiment and fertility for invention seldom excelled, have done efficient work in making in-

roads on diseases that have not yielded to other modes of treatment; or, if so, with far less readiness.

We do not question that claims have been made for electrotherapeutics that are fallacious and unsound, but, granting this, the work of the last fifteen or twenty years leaves much that can withstand severest criticism, and will compare favorably with the results obtained by any other method for treatment of disease, that receives the unqualified approval of the profession. The work of such men as Erb, De Watteville, Apostoli, Keith, Beard, cannot be turned aside with a sneer; while the universal testimony of the neurologists that this agent is indispensable to the successful treatment of a long range of diseases coming under their management, challenges our acceptance and respect.

The therapeutic effects of electricity, as far as they have been determined by physiological and clinical observations, may be classified as *stimulant*, or *electro-tonic*, *sedative*, *electrolytic* and *cathartic*. To these should be added the *cancerizing* action, since the galvano-cautery has a range of therapeutical application peculiar to itself.

STIMULANT ACTION.

The *stimulant* and *electro-tonic* influence of certain forms of electrical application is readily demonstrable, and is applicable to a great variety of conditions of bodily derangement. Where muscular tissue lacks tone, whether it be voluntary or involuntary, striped or unstriped, it can be readily subjected to the stimulating influence of the electric current, and in a variety of ways. For this purpose we can employ the static machine, the cathode of a continuous current, or the induced current completely interrupted or alternating, and, by the selection of one or the other of these forms, according as it seems best adapted to the condition, the functional rigor can be aroused in an organ in which such muscular tissue forms an essential part. And how universal are such tissues throughout the body! Thus the circulation in any part may be quickened, passive congestions overcome, congested organs relieved, and the evil results of malnutrition from excess or lack of blood in a part, or from feeble efforts at elimination, may be corrected by this action of the electric current. Functional disorders due to failure in vaso-motor control are especially benefited by such applications.

The good effects of such currents are daily demonstrated in the clinic by increased growth in paralyzed limbs, relief of pain, improved action of the viscera, and an increased sense of well-being manifested by the patient's manner and action. A torpid liver, a congested spleen, constipated bowels due to lack of secretion or feeble peristalsis, a congested or subinvolved uterus, chronic congestion of the ovaries, exhausted nerve centres with attendant hyperæmia or anemia, pro-

ducing those perplexing states of neurasthenia or spinal irritation are all conditions that can be helped by electric stimulus. And what have we to look to in our materia medica that will accomplish like good results with less damage to the organism as a whole? What can you apply or introduce that will reach the offending spot with as much precision, or do less damage by its presence while it gives the needed help? It certainly adds energy where energy is wanting, and when its work is done it leaves no debris behind to clog the further working of the part.

SEDATIVE ACTION.

As a temporary *sedative*, both the induced current and the anode of a mild continuous current are of service. They calm the neuralgic pains of many functional and organic disorders; they relieve headaches due to congestion or migraine; they allay the pains of muscular rheumatism, of pleurodynia and painful menstruation, and the lightning-like pains, so common in locomotor ataxia, are often more promptly and permanently controlled by this than by any other means. The manner of action through which this effect is brought about by the electric current is open to speculation. It may be in one of a variety of ways: by subduing a congestion which is the cause of the pain; by stimulating absorption or elimination of some deleterious effete substance; possibly by hastening the decomposition of an irritating product which is formed as the result of imperfect or misplaced metabolism; or the purely physical influence of vibrating movement induced in the nerve structure may account for the soothing effect. Whatever it may be, the calmative influence of these methods of electric application is daily exhibited in a great variety of painful affections, and sufferers of all ages and temperaments bear grateful witness to its efficiency in affording them relief.

ELECTROLYTIC ACTION.

The electrolytic action of the continuous current—that is, the power it has to bring about chemical decomposition and change the atomic arrangement in the composition of compound substances, is credited with very important therapeutic effects.

Electrolysis, by freeing the acid constituents of the tissues at the anode, and the alkaline at the cathode, is a convenient means for producing styptic or caustic action, which can be readily applied and accurately limited, and has of itself a wide range of application in the diseased body. But if, as is claimed, it can be proved by actual experiment or from clinical data, that all tissues lying between the rheophores of a continuous current are directly modified in nutrition and vital action by its influence, according to the quantity or intensity of the current, who is there so rash as to attempt, in this the infancy of

the rational use of electricity as a therapeutic agent, to mark out the limitations of its powers? No matter where, upon or within the body, disease has begun its havoc, the continuous electric current may be made to traverse the part and work such change as comes within the province of its powers. What these powers are over living tissues the physiologist and clinician must determine, but may it not be, with some reason, anticipated that normal tissue will be found to be stimulated to more vigorous action and resistance by its aid, while abnormal processes are checked, and substances foreign to the part, as effete matter or germ colonies, will be found unable to withstand the additional energy of this opposing force. If such change can be proved to be wrought by this mysterious agent in the secret laboratory, where cells and blood carry on their incessant interchange in harmony or discord, then no one will deny that in the continuous current we have a therapeutic agent which, for many disorders within the realm of both medicine and surgery, surpasses all other means at hand, and testimony in medical literature is accumulating in such abundance and from such high sources, as the result of accurate methods and critical observation, to the effect that herein we have a resource which will *cure* where hitherto we have only been able to *destroy* the part affected, that it challenges investigation, if not adoption, by every member of the profession.

CATAPHORIC ACTION.

The cataphoric action of the continuous current gives promise of aiding us materially in many ways. The introduction of medicinal agents into the body through the skin is oftentimes desired, and any method that will accomplish this with greater certainty than those now in use will be a valuable acquisition. The discovery of lanolin as an excipient for remedies applied by innunction was a great advance. But if, by employing the anode of the continuous current, we can hasten this process of absorption, and cause medicines to penetrate the cuticle, and thus reach directly the offending tissues, it will, in many instances, be of great service. This power to increase or reserve osmosis which the continuous current is said to possess will, if true, have abundant duties assigned to it in the removal of dropsical effusions from cellular tissues, joints and cavities. The contributions of Munk, von Bruns, Corning, Peterson and others, have furnished us with much interesting information on what they claim is the cataphoric action of electricity in carrying remedies and anesthetics through the skin, and it has even been suggested by a well known and highly esteemed surgeon, in a recent article, "that the principle of the process that causes absorption or diminution of the bulk of an uterine fibroid treated in this manner (*i. e.*, by the constant electric current), must be looked for in some form of electrical osmosis."

CAUTERY ACTION.

The advantages offered by the galvano-cautery over any other surgical procedure are chiefly found in the removal of growths of vascular or fungous character, or in arresting the progress of ulcers and malignant disease in passages of the body narrow and remote from the surface, like the nasal fossa, the Eustachian tube, the pharynx, larynx and external auditory meatus, the bladder, urethra and uterus. By this method the cautery snare, or knife, or scoop may be nicely adjusted to the necessities of the case, and when all is in readiness the heat is generated in the cauterizing tip with a definiteness of application and rage of intensity perfectly under control. In skilled hands its action is perfect and for such cases all other methods of treatment are but bungling substitutes.

Let us briefly enumerate a few of the results attained by electricity which have directly advanced the science of medicine and surgery. The physiologist, by the discovery of the laws of electro-tonus, has made it possible for us to determine the condition of a paralyzed muscle, thus greatly advancing the accuracy of diagnosis after injury or disease of brain, or cord, or nerve.

For the increase of our knowledge of *cerebral localization*, with the marvelous results in *cerebral surgery* which have followed so rapidly in its train, we are almost wholly indebted to the electrical experiments upon the brains of animals by a host of investigators. As a remedial agent it is claimed that:

It restores the action and increases the growth of paralyzed parts; it arouses vital action; it improves nerve conductivity; it contracts muscle; it hastens osmosis and absorption; it excites secretion; it quickens the circulation; it aids elimination; it allays pain; it makes hypodermic medication possible without puncturing the skin; it destroys superfluous hairs, removes warts, moles, sebaceous cysts and epitheliomas; it checks the ravages of lupus and other ulcers; it heals bed sores; it arrests keloid growths; it dissolves away cicatrices in the skin and along mucus channels forming strictures; thus, stricture of the lachrymal duct; thus, stricture of the Eustachian tube; stricture of the oesophagus; stricture of the os uteri; stricture of the rectum; stricture of the urethra, are all amenable to this treatment. "Not long ago physicians and surgeons of repute flouted the treatment of urethral strictures by electrolysis, now it is so generally and successfully practiced that scarcely any oppose it. . . . There is no comparison between the treatment of strictures of the urethra by the ordinary methods and its treatment by electrolysis. Should the permanency of the good results prove to be, as a rule, not so great as those recorded, still the calibre of the stricture remains

enlarged for a longer space of time than after any other form of treatment."¹

Like testimony from reliable sources as to its superiority over all other methods for the relief of strictures and the disorders consequent upon them in the other localities named, is not wanting.

It coagulates the blood in aneurisms, nevi and varicose veins.

Dr. John Duncan, surgeon to the Edinburgh Royal Infirmary declares "I have no hesitation in saying that the only justifiable method of treatment for cirroid aneurism is electrolysis."

We all know the claims of Apostoli and his followers for the treatment of uterine fibro-miomata by electrolysis, and it needs but be said that larger experience and improved methods have but confirmed and rendered more positive his earlier view, i.e., that it is a method for treating the majority of cases superior to all others, and in this he is ably backed by Keith and numerous lesser lights. Keith's latest conclusions are thus stated in his own words:

"This treatment *almost always* relieves pain. It *almost always* brings about diminution of the tumor, sometimes rapidly. It *almost always* stops hæmorrhage, sometimes rapidly. The results are *almost always* permanent and the growth of the tumor, if it be not lessened, is stopped. The general health is *immensely improved*. By *almost always* I mean *nineteen cases out of every twenty*."

The prostate gland, homologous in structure with the uterus and subject to like abnormal growth, has proved a perplexing problem when enlarged. Both physician and surgeon have expended upon it their best endeavors with but small reward; but some encouragement may now be held out to the sufferer and his physician, for recently it has been said, by one whose experience and opportunity for observation give weight to his words, "We have no hesitation in defining this as the only truly remedial treatment known for the hypertrophy of this gland in *restoration of its function*, operative procedure, looking, as is evident, to its greater or less destruction."

Such an array of victories claimed in the name of electricity demands of the profession proof or disproof.

But how are we to go about separating truth from error in these claims, and by what means can we determine with accuracy the capacities and limitations of this powerful force in nature for the treatment of disease? Hitherto we have, for the most part, acted like children in our dealing with the matter, for, armed with the trifling toys so often furnished for medical batteries, as heterogeneous in their variety and construction as the weapons of our revolutionary forefathers in

their first contests with the King's regulars, we attempted a crusade against the hidden mysteries of disease with a force, in its essence powerful, it is true, but hampered by our ignorance and the conditions under which we sought to operate it. No wonder that failure in cure followed such crude applications and that rumors of better results were met with incredulity.

We believe we are about to enter upon a more thoughtful age and are now as a profession prepared to soberly seek out and conform to those conditions which are indispensable for determining the effects of this all-prevailing force on the human body, both in health and disease.

THE FIRST REQUIREMENT.

The first requirement for a rational electro-therapist is that he who undertakes to practice it should be well drilled in electric physics and physiology.

In no branch of practical medicine and surgery can a knowledge of the fundamental principles of the natural sciences be safely ignored, but nowhere is such knowledge so indispensable to success as in the practice of electro-therapeutics, and yet how many of our medical colleges demand even an elementary training in physics as a condition for entrance? And how few furnish any instruction worthy the name in the regular curriculum?

How many physicians who are daily making use of electricity in their practice could explain the construction of the apparatus they are employing or the conditions it must comply with in order to generate a current? I have known a physician in high standing, a professor in a medical college, to use a galvanic battery or simple construction for a period of three months in making daily applications to a patient, and during that entire time there was no current passing through the conducting cords, he having failed to join the proper connections. And such mortifying instances, discreditable to the profession, could be related *ad nauseum*.

One who makes use of an electric battery should be as familiar with its construction and action as an oculist with his ophthalmoscope or an engineer with his engine; but how many expensive batteries, do we see lumbering up physician's offices, useless and set aside because of a corroded connection or a broken wire! It is perhaps fortunate so many accidents do happen to medical batteries, for electricity is a dangerous tool in the hands of one who knows so little of the conditions upon which its action depends.

Hand in hand with ample knowledge of electro-physics should go a familiarity with the action of electric currents on the normal living tissues. The laws of electro-tonus; the effects peculiar to the anode and the cathode; the variation in resistance of different tissues, all are essential factors in the information requisite to an in-

¹ Electrolysis in the Treatment of Urethral Strictures. New Eng. Med. Monthly, Dec. 1882.

² W. E. Stevenson, M.D., Woods Monographs. "Use of Electricity in Surgery."

³ Brit. Med. Jour. Feb. 12, 1891.

telligent use of electricity in therapeutics. Practical demonstrations and practical experience in electro-physiology as laboratory work under competent instructors, can alone fit the student for practicing intelligently this occult science. As reasonably might the physician, or he who dignifies himself by that title, attempt a cure by dealing out unknown drugs from his medicine case as to use electricity on his patients without such antecedent preparation.

THE SECOND REQUIREMENT.

The second requirement for securing a rational scientific position for electricity among therapeutic agencies is a uniformity in the means employed for its application to the body.

We have at present no less than fifty manufacturers of electric batteries and appliances for medical use, and no two of them have adopted the same pattern or means for generating currents. On the contrary, trade enterprise has stimulated inventive ingenuity to produce diversity rather than uniformity in order that it might be made an additional argument for the sale of that particular variety of instrument. Many physicians in this, as in many other therapeutical measures, take suggestions from non-medical men as to what instruments they require and how their patients should be treated. Those members of the profession, who have from personal experience, discovered the essentials of a medical battery rather than the instrument maker, should be looked to for information as to what are the best and most suitable forms of batteries for therapeutical purposes. Some standard should be adopted for a constant current battery, an induction coil, a volt meter and a milliamperemeter.

It is rare, if any two physicians at the present time, who daily employ electricity in their practices, do it in like manner. They cannot therefore compare results since they are not assured that in the treatment of similar diseases they have subjected their patients to the same conditions. Should I in Michigan wish to test upon my patient the effects of electric treatment claimed by a fellow practitioner in New York or elsewhere to be successful, how can I know that my "McIntosh" is furnishing the same current that he used from his "Kidder," since our milliamperemeters have never been compared, and the voltage and resistances are not reported?

Recently effects have been reported in a prominent journal by an eminent electric therapist as having been brought about by the use of the induction current that seems to me incredible, but am I justified in denying his statements until I know what form of instrument he made use of, and have myself used the same in like manner and so determined the inaccuracy of his conclusions?

Nothing differs more than the intensity of the

currents generated by induction coils; therefore, without a standard instrument, which is the same wherever used, no progress toward uniform results can be made.

Until within a few months there has seemed to be no way open for securing this much desired harmony and uniformity in electro-therapeutical appliances, but the organization of an *American Electro-Therapeutical Society* in January last gives promise of better things, and may we not hope that through the labors of this organization we will soon receive definite instructions as to the best instruments to make use of and the best methods for applying them?

In this connection let me suggest that the tendency should be toward the simplest and least expensive instruments consistent with efficiency. Many of the obstacles to the progress of electro-therapeutics have arisen from the high price, complexity and frailty of the instruments furnishing the current.

One drawback, and that perhaps the most fruitful in retarding good work, lies in the use of fluid batteries for generating both constant currents and the primary circuit for induction currents. Many of the annoyances arising from this source, such as the deterioration of the fluids, the consumption of the elements when the battery is not in use, the corrosion of connections in the circuit, can now be overcome by using a dry cell. I have for months made use of a dry cell for running induction coils and found it very satisfactory. You who have occasion to use portable batteries can readily appreciate the advantages to be derived from substituting a dry for a wet cell in all portable machines. Even for stationary work the dry cell is superior on account of its cleanliness, but in matter of durability it requires some improvement.

Nothing, in my opinion, will eventually be found so convenient for office work as the use of commercial currents.

The Edison incandescent current with its constant voltage of near 110, affords an admirable source of electric power for electrolysis, cataphoresis, inductive stimulation, and cautery purposes. By a very simple appliance for changing the voltage I have used this current in my office for more than two years, and the same method applies quite as well to the currents of equal or less voltage from other sources, whether they be alternating, as the Thomson-Houston dynamo, the storage battery, or any form of primary battery plant that has sufficient electro-motive force.

To sum up, therefore, the ideal conditions for establishing electro-therapeutics on a scientific basis, they are:

1. A source of electric power, as a dynamo or storage battery with a constant unvarying voltage, from which the current is conveyed to hospitals, physicians' offices or patient's houses.

2. A *current regulator*, rheostat or modifier by which the strength of the current may be adapted to the required needs of individual cases, and this should be of convenient size, durable in construction and simple in arrangement. The simplicity, economy and efficiency of such appliance would insure its being readily adopted by the profession.

3. A *series of electrodes* which should be constructed according to a fixed standard as to size and shape, and they should be made of material which is cheap, readily conducting, and non-polarizable.

4. All should make use of a *standard milliamperometer* for determining "strength of current" and a *coulombmeter* for "quantity" or dose.

Complying with such conditions as these, progress in determining the limitations of electricity as a therapeutic agent would advance with rapid strides. The incandescent electric light plants with low electro-motive force are very common throughout the country. The physician and dentist finds the current extremely useful in his office. It illumines his apartments, it runs his motors, it lights the tiny lamps with which he explores the cavities of the body. It heats the water for his sprays and douches. It will not be long before it will be made use of by the many as it has been for some time by the few, for all the applications of electricity to the human body, since it does away with a host of difficulties that have up to the present been of such magnitude as to make electric applications either a burden or a farce.

RELATION OF GYN. ECOLOGY TO NEUROLOGY.

Read in the Section of Gynecology and Obstetrics at the Fortieth Annual Meeting of the American Medical Association, held at Washington D. C. May 1901.

BY WM. B. DEWEES, A.M., M.D.,
OF SALINA, KANSAS.

The intimate relationship which exists between diseases of the organs in the female pelvis and the general nervous system has not yet been elucidated. Though as early as 1858 Brown-Séquard pointed out the dependence of insanity, epilepsy, hysteria and other affections, upon organic disease of the female generative organs, Baker Brown put these teachings into practice and furnished clinical proofs of their correctness. He, however, fell a martyr to the professional bigotry which his doctrine excited. Now, however, that the rancor of that day has died away, his book on "The Curability of Certain Forms of Insanity, Epilepsy, Catalepsy and Hysteria in Women," can be read with interest and modified by the later revelations of science, his teachings can be followed with safety.

The influence of the unhealthy uterus and ovaries upon the development of the diseases of other organs of the body by virtue of the neuric forces through the intermeddling of the complex generative nerve-circle, the sympathetic and the cerebro-spinal systems of nerves, is a matter which I am led to believe has received very little attention at the hands of practitioners as evidenced by the fact, that I mailed a carefully prepared letter of inquiry to two hundred and fifty of the most noted practitioners of the United States, and the only responses came from Dr. Charles A. L. Reed, of Cincinnati, O.; Drs. Barton Cook Hirst, William Goodell, James Tyson, John V. Shoemaker and R. J. Dunsigson, of Philadelphia, Pa.; Drs. Trail Green and Charles McIntire, of Eastern, Pa.; Dr. C. Henri Leonard, of Detroit, Mich.; Dr. Henry O. Marey, of Boston, Mass.; Drs. J. Taber Johnson and Irving C. Rosse, of Washington, D. C.; Dr. R. H. Thomas, of Baltimore, Md.; Dr. P. Bryce, of Tuscaloosa, Ala., and Dr. Alexander B. Shaw, of St. Louis, Mo. I had hoped to be able to present valuable data from this source, but the responses being too limited in number, and too meagre with facts, to be of any material value to science, they have therefore been omitted.

For more than a decade my attention has been directed to the interdependence between diseases of the female pelvic organs and diseases of other organs. Which is the cause and which the result is not always possible to determine, the relationship evidently varying in different cases, for while in a large percentage of cases of neurosis in the female, interdependence of diseased conditions through the neuric forces could be distinctly traced and finally lucidly established, by the subsequent course and termination of those cases; in other cases the causes could be seen to depend upon a condition of malnutrition alone.

My authority for coming to this conclusion may fairly be questioned, and therefore I give my reasons. If I am consulted by a female patient complaining of voice, heart, brain or other troubles in whom examination reveals physical signs of diseases of these organs, and if in the same patient I find uterine or ovarian disease, and if the voice, lung, heart, brain and other troubles disappear upon treatment of the uterine or ovarian disease without any other medical aid, it is but logical to conclude that the voice, heart, brain and other troubles were dependent upon that of the womb or the ovaries. This being conclusively shown, by a few illustrated cases selected from a large number and appended hereto, it follows that what may have been a coincidence becomes a sequence, and the conclusion at which I have arrived is inevitable.

Far be it from me to assert from my experience that all cases of neurosis in the female are dependent upon lesions of the generative organs;

* Dr. Charles A. L. Reed, of Cincinnati, in *Buffalo Medical and Surgical Journal*, May 1882.

but that a very large percentage of the neurosis are dependent upon local disease within the pelvis is fully warranted. It is not my intention to theorize upon the subject, to waste useful time in useless conjectures, my object being only to draw attention to the clinical fact and to endeavor to awaken the medical mind to its great practical importance.

The hindrances to the true understanding of the relation of gynecology to neurology are to be found in:

1. The unsettled state of physiological and pathological history.
2. The absence of a thorough knowledge of the anatomy of the reproductive nervous system, and of data regarding the interdependence of menstruation and ovulation; and last, but by no means least.
3. The existing ignorance concerning the neurosis attendant on lesions of the female reproductive organs.

Confronted with these facts we must acknowledge that we grope for the truth like the blind, and are at a loss for philosophical explanations based on historical and experimental research.

Every experienced gynecologist will upon reflection admit, that there is nothing very extraordinary in the implication of distant organs in connection with and dependent upon utero-ovarian disease through the neuric forces, since in the practice of all such, instances are not wanting wherein tissue changes have been produced at a distance by ovarian or uterine irritation. Medical literature is full of examples of acne rosacea, pharyngitis, bronchitis, epilepsy, cataplexy, hysteria, melancholia, mania, insanity, diseases of the joints and muscles of the extremities, lesions of the heart and lungs, paralysis, etc., superinduced by reflex irritability of the intrapelvic organs. It is quite true that the number of women dying from these complications is now much less than formerly. We have learned better to differentiate and treat disease, but it is doubtful if we fully appreciate the consequential relations which one abnormal condition bears to another. While in many of these interdependent complications relative to the subject, the disease of distant organs bears to intrapelvic disorders the relation apparently of effect to cause, and you can observe for yourself the fact, yet the manner in which the changes are brought about may remain an open question.

Neurosis may be defined as an exaggerated intensity of both the sensor and the motor forces, and may be induced by *a*, developmental, or *c*, pathological causes.

a. Psychological causes may act by an impressionable idea allowed to become fixed by an active fancy or imagination, producing a diseased condition of the imagination, whencesoever, idealization produces neuric impulses.

b. Developmental causes may act by the rapid and swelling growth of the intra-pelvic organs as manifested by gestation.

c. Pathological causes may act by a fluxionary movement, as in suppressed menstruation; the presence of the neoplasm of the ovaries or uterus; misplacement, engorgement or inflammation of these organs. Pathological causes may also be produced by muscular laxity of the abdominal or spinal muscles, or both—unquestionably the most prevalent forerunner of all causes—destroying the primitive erectness of the body, the normal obliquity of the pelvis, the maintained ascendent position of the internal viscera from below upwards, resulting in a mechanical displacement of the visceral status, involving a train of both physical and functional derangements of the pelvic organs.

All of these causes may and do pervert the normal forces of the complex generative nerve-circle to disturb the whole economy, and the persistence and permanence of these causes may develop the emotional influences to an uncontrollable degree, as evidenced by that undefinable neurasthenia known or designated by the term hysteria, or finally affect the mind and even destroy reason, as evidenced by melancholia or insanity. Thus we have the sympathetic neurosis, hysteria, as the analogue of that cerebral neurosis, insanity, both alike dependent upon pelvic neurosis, which fact goes to prove conclusively the interdependence between gynecology and neurology.

In the language of Dr. Chas. A. L. Reed, of Cincinnati, O., who, speaking of the female organs of generation, says: "It may not be amiss, however, to recall the fact that all of these organs have intimate connection with both the sympathetic and spinal systems of nerves, and that these systems of nerves in turn communicate with each other. Through these instrumentalities morbid impulses originating in diseased conditions of the intra-pelvic viscera may be telegraphed, as it were, either to those centres which preside over nutrition, or to those other centres which govern sensibility and motion. In the former instance the sympathetic system furnishes the route of transit, and the result may be observed in the modified calibres of all the blood-vessels generally; in the perverted activity of all the glandular organs; in the unrhithmical movements of all the other viscera and gland ducts, or in a more or less marked interference with ultimate tissue nutrition. In the latter instance the cerebro-spinal system of nerves is involved and the results are pain, and may be motor disturbances of either the voluntary or reflex character. In either case the brain is reached, and we cannot fancy that impressionable organ receiving an impulse in excess of normal without sustaining more or less functional disturbance, whether that

disturbance be manifested by psychic phenomena or not. The perpetuation of this disturbing influence through the persistence of the initial lesion in the distant viscera is sufficient to convert the functional disturbance of the brain into an organic change involving that organ."

Here let me digress to state in this connection that I regard thought and all mental actions to be the results of brain elimination, and in proportion to the quantity and quality of the grey matter of the brain so will be the intellectual capacity of the individual. Any change, either progressive or retrogressive, in the metamorphosis of the ultimate cell structure of the brain will upset that symmetrical balance of action known as sanity, and the various grades of insanity are developed. I regard the brain as the being—the man—all else, limbs and organs, as servants moved and compelled to do duty by the nervous mass. Oken asserts "that the animal is naught but nerve." Can you gainsay him? From the nervous mass called brain issue two, and only two forces, one sensor and the other motor.

Returning to our subject, it may again be argued that, first, there is a derangement and impairment of the complex nervous system and neuric function from the utero-ovarian or pelvic diseases, followed by impaired digestion and mal-assimilation as a natural consequence. Then comes the persistence of disordered hepatic, renal, etc., circulation, the invasion of the contents of the digestive tract by the *tortuæ arvensis* and consequent fermentation with its attendant disorders constantly increasing. Finally, by excessive irritability of the nerve-circle presiding over the orgasm function there is developed a morbid sympathetic or cerebrospinal action, which may be curable because there is simply supernatural reflex irritability,—a sympathetic or cerebral neurosis dependent upon pelvic neurosis.

APPENDIX OF CASES.

Case 1.—In May, 1886, I was summoned to take under care the wife of a farmer, aged 54 years, and the mother of two sons, who had passed the menopause at 46, and always enjoyed good health up to about eighteen months prior to my seeing her, when she received some injuries by being thrown from a carriage by a run-away horse. Her suffering then being confined chiefly to her knees, which had become very swollen and painful, presenting all the local characteristics of acute articular rheumatism, for which disease, (the husband stated), nine different physicians had treated her during the eighteen months of her confinement to bed, without any apparent benefit, aside from the temporary relief of pain. A timely and careful examination revealed a complete protrusion of the uterus, greatly congested, from the vulva of the patient, who was lying on her back, and both her knees swollen to three times their normal size, red in appearance and very painful to the touch, so much so that the bed clothes had to be supported above them. She was very much emaciated by her long suffering and confinement. I noted my diagnosis proclentia uteri, complicated with neursthenic insufflation of both knees—hys-

tered knees. I repositioned the uterus in a reclining posture by proper mechanical support and painted the knee joints twice daily with oil of peppermint which, together with attention to diet and elimination, constituted the entire treatment. The patient made rapid recovery, the swelling abating within six weeks to leave her bed and enable her to go on a distance of ten miles, with all the appearances of being a well woman, and has remained well ever since.

Case 2.—Miss _____, aged 21 years, was supported into my study by her father in mid-September, 1886. The history given to me of her case was that she had been then under treatment for consumption and hysterical epilepsy for six years, without benefit, but on the contrary was gradually failing. The girl's appearance was pitiable in the extreme. Large drops of cold sweat oozing from her emaciated face, which bore a haggard, worn expression of extreme anxiety; her extremities swollen, and abdomen distended until it had become painful. Of late she had been having frequent hæmoptyses with dyspnoea, painful chest and great increasing weakness, backache, irregular and painful menstruation, leucorrhœa, anorexia, hacking cough, and a weak husky voice. She was now seized with a hysterical plegia, convulsion, and I had to defer further examination until it had passed off. After which auscultation revealed areas of dulness with subilar rônchus over both lungs, prolonged expiration and feeble heart's action. Examination per vaginam showed a prolapsed retroflexed and inflamed uterus. The treatment consisted of special attention to the uterine condition, rest in bed for several months, hot water douches and nourishing diet, with finally placing a Smith Hodge pessary, and her recovery was complete in six months, she being robust and well ever since.

RAPID DILATATION AND CURETTING.

Read at the Session of the American Medical Association, held at Atlantic City, N. J., June 12th, 1890.

BY J. G. CARPENTER, M.D.,
OF STANFORD, KY.

This is a subject of no little importance to the profession; the voice of warning has already been raised against it, might be said, the wholesale use of rapid dilatation and curetting or the practice of these in the hands of those who are unskilled in their use and are poor diagnosticians of intra pelvic disease; in fact, these therapeutic measures have been severely condemned by distinguished abdominal and pelvic surgeons, chief of whom is Dr. Joseph Price of Philadelphia. He has written a most excellent paper on "Certain Causes of Major Pelvic Troubles Traceable to Minor Gynecology."

That they have been severely condemned is no argument against their proper use; that they have been shown to be instruments of great harm in the hands of the roteness, the inexperienced, and unskilful, and met with so great censure by intra pelvic surgeons so eminent, will deter many from their former practice and save the female the ordeal of abdominal sections. It may be truthfully stated that when the intra pelvic affections threatening life, arising from rapid dilation and curetting, as well as the improper use of the uterine sound and trachelorhopy, and abuse of pes-

saries and caustic applications to the endometrium, are realized and appreciated by the so called pseudo, or minor gynecologist, there will be fewer cases with their ovaries and tubes in bottles, instead of their normal habitat.

Unfortunately for humanity so many graduates as well as senior members of the profession appropriate to themselves the stupendous title—Gynecologist, and seem to think the essentials to a successful practice and fortune are the speculum, uterine sound, curette, Goodells' dilator and Thomas' retroversion pessary, and handle the sound with as much recklessness as the dude twirls his cane, and imagine all intra pelvic diseases are uterine. The ultima thule is fewer and better practitioners, less number of medical students, fewer and better medical schools with enlarged hospital experience, and instead of a three years course of study being compulsory, make it five years or longer, with abundant clinical or hospital experience and gynecology learned and taught before it is put into practice. Unfortunately only the minority of every graduating class have had proper clinical experience to begin practice; the majority seldom reach mediocrity; they start wrong, go wrong and end wrong.

There are cases demanding rapid dilatation, or curetting, or both, and the physician would be direct of duty not to use them. Their proper use must be commended, their improper use condemned.

The scriptural adage, "be temperate in all things" is highly appropriate and essential in the practice of minor gynecology. That the minor gynecologist too often ignores or is incompetent to detect existing intra-pelvic diseases when practicing these methods, or by the practice produces intra-pelvic diseases, there can be no doubt, just in the proportion to the abuse of rapid dilatation and curetting and other minor measures does he become a *feeder to the major gynecologist or abdominal and pelvic surgeon*, only a few weeks observation and study and analysis of cases in the practice of men in the profession like Drs. Joseph and M. Price, Charles B. Penrose, E. E. Montgomery and Hoffman of Philadelphia, and T. A. Emmet of New York, would convince any "doubting Thomas" that "certain causes of major pelvic trouble are traceable to minor gynecology."

One class of patients, you will find the major pelvic trouble traceable to a dirty confinement, or too early leaving bed and resuming household duties or hardships, or other minor imprudences; to imprudences during the menstrual molimen and frequent abortions; others have had a gonorrheal infection or sexual abuse; others date origin of the ailment to an improperly adjusted pessary; to the use of the sound or probe; caustic application to the endometrium or os; others to operation on cervix (trachelorrhaphy); others to

rapid dilatation or curetting, etcetera etcetera. That the general practitioner too often generalizes in place of specializing, and the specialist too often specializes instead of generalizing, there can be no doubt, and that the minor gynecological tinker, tinkers with his patients until major pelvic troubles arise, and his patients pass into the hands of the pelvic surgeon is *self-evident*. These major pelvic troubles, many of them like Banguo's ghost, will continue to arise, because they will not down or cease until the pseudo gynecologist ceases to tinker. These questions may be asked, are forcible dilatation and curetting ever essential, and when are they indicated? Answer, yes. When and by whom should they be used? They should be used by the aseptic physician, or surgeon, who has been taught by practical experience and differentiation the pros and cons for these measures, and as a dernier resort; but some times, as in case of hemorrhage and putrid placental infections, their use as means of primary remedial importance must be considered, in order to save life and prevent sepsis; and with the aseptic instruments, through the aseptic vagina, os, and cervix and when dilatation or curetting is accomplished, make the endometrium aseptic with hot water, the bichloride or boric solutions, iodine and glycerine mixture (Churchill's tincture of iodine), the liquid vaseline and oil of eucalyptol, or menthol solutions, the insufflation of bismuth, subnitrate, or iodoform; the vagina kept aseptic "pro-re-nata" by hot antiseptic douches and aseptic vulva pad to prevent decomposition of the uterine discharge and infection. Before forcible dilatation or curetting are resorted to, the patient should be given a hot water and soap bath, purged freely, and placed in bed at rest twenty-four or forty-eight hours, and the vagina douched with hot antiseptics every six or twelve hours. After the operation, the patient should be kept in bed one or more days, until all manifestations of a local or constitutional reaction have subsided and the patient free from danger; the operation should never, never, be done in the private or consulting office, and never by the pseudo-gynecologist; nor more than intervals of ten or fourteen days, at least five days before and after the menses, and when the disease is limited to the uterus *per se*, an entire absence of disease in the pelvis.

These measures, though sometimes indicated and though no intra pelvic inflammation is present, may and have done incalculable harm by setting up pelvic disease even though slight; no dilatation or curetting should be practiced unless absolutely required by patient to save life. Rapid dilatation or curetting are distinct traumatism, and all the dangers incident to septic absorption may attend them that follow any other violent procedure. Dr. Joseph Price states in reference to rapid dilatation: "This conclusion reached

inferentially has been abundantly confirmed on the operating table by much of my later pelvic work. In a number of cases with a history of preceding dilatation, the after-operation has exhibited an inflammatory condition of affairs as complicated as any other; in my experience some of the dilatations were done with pre-existing disease which was made worse by the interference, while others were done simply to relieve the dysmenorrhœa and resulted in the establishment of a complicated surgical disease in which operation was necessary to save life. All in all, I believe that judged simply by its remoter effects, the operation of rapid dilatation is a dangerous one and results oftener in subsequent harm than in lasting good. The surgical injury to the cervix which it is the intention to remedy by Emmet's operation. Dilatation with curetting of the uterus have placed to their credit a long series of major operations."

The writer saw a unilateral laceration, left side, caused by the dilator, extend almost to the fornix vaginae. No doubt many experienced physicians have dilated with good results, such men as Emmet, Gilwily, Goodell, DaCosta, Baldy, Ashton, Noble and others who are not so eminent, but they have been taught gynecology in all its relations and know the when, and how and the pros and cons. Dr. DaCosta states: "Dr. Goodell has reported to this society Philadelphia County Medical Association many cases in which forcible dilatation has been used with grand results. I have used forcible dilatation in many cases and have never had bad results. The reason is that when I began the study of gynecology I was taught how to use it properly, and not to use it in every case. The dilator is a surgical instrument and one which must be handled carefully. You must know how to do your work before you attempt to use it. My teaching is, when there is violent inflammation in the pelvis not to do any operation on the uterus and to hesitate to use the sound." "He should have said never use the sound."

Dr. William E. Ashton: "The question of the use of the dilator depends on one or two facts. First, as to the condition of the uterine appendages and their surroundings; secondly, properly selected cases. I believe that when we have the pelvis perfectly free from local disease in cases where the uterus is strongly anteflexed and perfectly movable, and upon the introduction of the sound we find there is a point of intense pain at the internal os, we shall find in a certain proportion of cases that good results are obtained by the dilator. The vast majority of cases of dysmenorrhœa are cases which have a distinct tubal or ovarian origin. It would be absurd to rapidly dilate in such cases. It should go on record that the uterine sound should only be used by men who have a thorough knowledge of the pathol-

ogy of the pelvis and who can appreciate the great danger incident to inflammatory troubles in the uterus."

Dr. C. P. Noble: "I should be loth to give it up—rapid dilatation—I have never seen any harm follow rapid dilatation in any case. This is due to the fact that dilatation has been used in cases in which the disease is limited to the uterus. I agree that it is useless and dangerous to dilate the uterus when tubal disease is present. In uterine disease it is capable of a great deal of good."

Dr. J. M. Baldy: "I should be loth to give up forcible dilatation in certain cases. It should not be done in every case of dysmenorrhœa, for the vast majority of cases are due to ovarian or tubal disease. I believe that in the vast majority of cases where trouble follows the use of the dilator, there has been pre-existing pelvic trouble. I do not think that a carefully done dilatation in a healthy pelvis will do harm. It is admitted that it will tear uterine tissue, but that this can cause trouble unless the wound becomes septic I am not prepared to admit."

Dr. Price, in referring to the article of a minor gynecologist, states in debate Philadelphia County Medical Society: "He is the great mischief doer. He tinkers, dilates, cures, passes the sound and in four to six weeks he Dr. Price gets a telegram to come and open the abdomen to save the patient's life; that the woman is leaking; that she has a pulse of 130 to 140, with temperature of 104°. This recurs weekly; also stated of specimens in that jar removed during the month of August, 50 per cent. followed dilatation, closure of cervix, the use of the sound and curette. These specimens have come from four clinics in this city Philadelphia, and from ten prominent gynecologists. They all had sections to save life and all were greatly complicated operations. These fibroids in the jar had pus in them, the result of electricity. This private office work has a great deal to do with it. Many of these men are simply cervix feelers, and never find anything above it. There may be a mass larger than the uterus on one or both sides which they fail to find. They are not anxious to find them and would not be troubled by them or capable of dealing with them if they struck them accidentally."

This state of affairs existing in Philadelphia. The havoc wrought by the minor gynecologist could be doubtless estimated *ad infinitum* throughout the world. Dr. Joseph Hoffman states, I have put on record, in the Obstetric Society, a case where the uterus was perforated by the curette. I have seen to day two patients that have been treated by the curette and from whom I have removed the appendages. In one case that I know of the uterus was torn by the dilator, then a sponge tent was put in and allowed to remain, I

do not know how long. You know the rest. In the case in which the uterus was perforated by the curette, the operation was done by a gynaecologist of considerable experience. Nevertheless the uterus was ruptured and peritonitis was brought on and abdominal section was necessary to save life. I have to day two other women who were treated by minor gynaecologists; they were both left miserable. In one the vagina is much contracted and the pelvic viscera are certainly affected. In one of these cases especially electricity was used ad nauseam. The history is this: first dilatation and scraping; then closure of the perineum; and then the opening of the abdomen. Dr. Emmet for a decade or more gave the danger signals of minor gynaecology ignorantly and thoughtlessly practiced, but the warning has only been heeded and appreciated by the few. The many, it might be truthfully said, have gone on their way in mid night darkness causing pain and anguish, destroying important organs, wrecking constitutions and loss of life. Emmet's (*Principles and Practice of Gynaecology*) is replete with aphorisms of wisdom lightening the pathway all along the line and is to the major gynaecologist a "sermon on the mount," but the pseudo-gynaecologist or gynaecological tinkers are deaf and myopic and would not turn from the error of their way "though they had Moses and the Prophets to warn them." Dr. DaCosta states, "then in regard to the curette, these usually have a sharp cutting edge. Such an instrument is hardly safe for an able practitioner to use and is not safe in the hands of the unskilled person; when inflammation extends from the uterine cavity to the tubes, after the use of the curette, it is not so much the instrument as the man who uses it." Dr. Hoffman states "the curette in some cases is a necessary evil which we cannot do without. I have found it useful in getting rid of putrid debris from miscarrying uterus in the early weeks of pregnancy, when the use of the finger is thoroughly clumsy and painful; if not impossible, without previous dilatation with tent, I can say I have had no bad results I know of."

Dr. Bddy: "The curette, I think is a valuable instrument, but it is abused and used indiscriminately. After abortion I found it most valuable. In some cases of chronic endometrial disease it is valuable. I believe it will remove almost all necessity for intra uterine treatment. I think the dull curette useless. The only rational treatment is the sharp curette. The sharp curette can be used with as little danger as any other instrument if used properly in skilled hands."

Dr. C. P. Noble: "Why we should give up the curette, I cannot understand. There are many cases of hæmorrhage of the uterus due to uterine disease purely, where there is no ovarian or tubal disease. In such cases, the curette will permanently control the hæmorrhage." (The

consensus of opinion is that the dilator and curette are valuable instruments in skilled hands, but otherwise are agents of potent evil.)

When so skilful and erudite a surgeon as Dr. Emmet has had harmful results follow forcible dilatation and curetting, with all his care, diagnostic and operative skill, painstaking and prophylactic measures, one is forced to believe inferentially that the gentlemen who have been quoted would certainly have had experience similar to Dr. Emmet had they followed up their cases, corralled them, and hunted for after claps or evil results. I have found it often (uterine dilatation) very serviceable for arresting hæmorrhage, particularly when due to soft growths, or to some diseased condition of the canal. It is of great value after a tent has been used to increase the dilatation at the time of operating for the removal of an intra uterine tumor. Ten or fifteen minutes will often be sufficient to effect the necessary dilatation for purposes of exploration, but as already stated, rapid dilatation should never be employed unless the case is urgent. If pregnancy exists and a tent has already been used, or if there should be a hæmorrhage, there will be less risk from rapid dilatation. Under other circumstances, it is always attended with the danger of existing inflammation. (Page 36, Emmet's *Principles and Practice of Gynaecology*.) In hospital practice, when I could control the movements of the patients, I have long employed sponge-tents to bring about a reduction in the size of the often enlarged uterus. This mode of practice is original with me, and from long experience I have found it most satisfactory whenever employed under proper circumstances. The object is to bring about by pressure an alterative effect in the mucous membrane and indurated tissue, to excite contractions of the whole organ and to lessen the circulation in the uterus by means of the profuse watery discharge which is invoked. (Page 140.)

It is equally beneficial, if not more so, when there exists no enlargement, since the disease is then confined chiefly to the cervix, or at least to that portion of the canal below the internal os. By dilating the canal thoroughly in these cases, it will open at the rugæ, so that the agent applied can be brought directly in contact with the mouth of each crypt, and every portion of the mucous membrane. This cannot be done under ordinary circumstances, and the fact will explain the negative result, frequently observed after operations made through the undilated os, for the nearer the uterus approaches to a natural state the deeper will these folds be found. In reference to local treatment Emmet states: "We should always have the fear of cellulitis before us." No portion of the body has suffered more from the over zealous interference of ignorant practitioners, and from the carelessness of those who,

though not ignorant, fail to make such a thorough investigation of their cases as is essential to their successful management. Under the guise of surgery, the uterus has been subjected to a degree of malpractice, which would not be tolerated in any other portion of the body. Its cavity has been and is to day made the receptacle for agents so destructive, that it seems difficult to understand how their evil effects have escaped observation. But I trust we have already passed the heroic age, and that in the treatment of uterine diseases, we may be hereafter governed by the same rational methods as should apply in every branch of medicine, that is, we may simply, as we term it in this country, exercise our "common sense."

Indications for Dilatation.—Dysmenorrhœa due to cervical stenosis; its cause should be reached by exclusion. There is sometimes primary stenosis; all conditions being normal; the mucous membrane engorged at the menstrual nixus, constricts the internal os, and when there is endocervical and corporeal mentritis in the virgin or nullipara, the stenosis may become much aggravated, especially if, in addition to the hypertrophy and hyperdistention of the mucous crypts with closed orifices and pent-up sections, there is hyperplasia of the submucous connective tissue. To one familiar with the occlusion of the nasal chambers from chronic and hypertrophic rhinitis, it can be readily perceived how a similar condition of the uterus mucous membrane could cause and aggravate a stenosis of the internal os, and how the displaced uterus in the form of versions, flexions and obliquities, single or combined, could cause stenosis like the flexed or dislocated portion of the nose, and be amenable to restitution and dilatation to straighten the uterine canal, making it more patulous; the pressure opening the orifices and emptying the distended crypts of their contents, allowing their walls to collapse, besides causing absorption of effused fluid and unorganized lymph, and by straightening the uterus, also straighten the arteries, allowing increased nutrition, by rectifying the veins, relieve passive congestion, removing the engorgement from the over-loaded capillaries, and in a similar way, increase the functions of the lymph channels. Not only may an enlarged uterus be benefited this way, but, also a uterus of natural size afflicted with endometritis. When the walls of a displaced uterus are straightened by dilatation the womb is much more easily retained in normal position, gets more patulous at the internal os. Some operators would recommend dilatation for infantile uteri, to increase their nutrition and size, but we doubt the expediency and believe the weight of authority is against it, since their cause is tubal and ovarian. After dilatation the distended crypts can be scarified or punctured; dilatation is often essential for diag-

nosis of intra-uterine growths and foreign bodies, and as a preparatory step to curetting. Emmet speaks of the beneficial effects of forcible dilatation for malarial congestive hypertrophy of the uterus. We can also often obtain the pressure, size and positions of intra-uterine growths, and use it as a preparatory step to removal of these growths of foreign body. Dilatation is essential to wash out the uterus when there is sepsis, and in conjunction with curetting to remove septic material and arrest hæmorrhage. Rapid dilatation should never be used unless the cause or case demanding it is urgent. Emmet states if pregnancy exists and a tent has been already used, or if there should be hæmorrhage, there will be less risk from rapid dilatation than under other circumstances; it is always attended with the danger of exciting inflammation.

Indications for Curetting for Diagnosis.—Presence or absence of growths or tumors in uterus. Removal of portions from cavity of uterus for inspection. (Skene.) In chronic endometritis, the removal of granulation tissue, as in granular conjunctivitis to open the engorged and distended crypts, and relieve them of their contents and free the lumen of the canal; to remove fungous, or foreign growths, and retained septic placenta; to arrest hæmorrhage. In malignant disease of the cervix, after removing all growth possible with the scissors, the Sims curette, or Thomas' wire scraper, followed by the paquin cautery, becomes a valuable adjunct. Emmet states Sim's scraper has too sharp a curetting edge and causes much bleeding. When the follicles of Naboth undergo cystic degeneration and are detected by their rough and uneven surface they should be ruptured with the curette, used with mild force over their surface. In diagnosis of intra uterine growths, the curette is claimed by some to be a valuable diagnostic measure, but it removes both diseased and normal tissue.

Thomas' wire curette, and Emmet's scissors-shaped or forcep curette are recommended as the safest and most expeditious. The dull or wire curette from the friction or pressure effect produced, may change the nutrition of the affected parts by retraction and absorption of exuberant tissue, and soft villous growths. In cases of old cervical lacerations with multiple papilloma and warty excrescences, the sharp curette has proven a most valuable instrument and did beautiful work by removing them; chronic anhydrous acid was then applied to the bases with the best results, and no evil sequelæ, in the uterus of a woman 70 years old, in the fall of 1889; patient is still living and enjoying good health. Emmet's forceps curette can only remove the growths projecting above the uterine surface; it crushes the diseased tissue in its immediate grasp; in addition, too, it can be used as a dilator when neces-

sary. Of the Recamier curette modified by Simpson, Simon and Simms, it is said that the ingenuity of man has never devised one capable of doing more injury. Women suffering with intra-uterine growths are, as a rule, quite anemic, and very susceptible to septicemia and peritonitis after curetting. Emmet states that he has known peritonitis, cellulitis, and pelvic abscess and even death, to occur on removing these growths from the uterine canal with the curette, and in every instance the operator was dextrous in the use of the instrument. Inflammatory disease may extend by continuity of tissue into the tubes, ovaries and peritoneum from the uterus, producing peri- or parametritis, or these can be caused by intra-uterine instrumentation, *per se*, or the dilator and curette. If uteri free from intrapelvic complications only were dilated and curetted under proper conditions, and were a thorough and intelligent, digital and conjoined manipulation made in every case, before instrumental treatment is used, pelvic disease would be detected, and non-interference would be the rule, and major pelvic operations to save life would be less frequent.

When the minor gynecologist ceases to tinker there will be far more tubes and ovaries remain in the pelvis. It is to be hoped that the millennium is at hand, that the "goats will be separated from the sheep," and to the pseudo-gynecologist the scriptural injunction proclaimed "depart ye cursed, I never knew you," will be fulfilled, and that woman will keep her normal uterine appendages instead of having them removed and placed in bottles. The more experienced and skilled the diagnostician is, the less often will he resort to dilatation and curetting; conversely, the more ignorant and unskilled the operator, the oftener will he use these measures and greater will be the disaster to health, happiness and life.

WHEN IS ANTISEPSIS A FAILURE?

By F. E. Ery's, Section of Obstetrics and Diseases of Women, at the First and Annual Meeting of the American Medical Association, held at Washington, D. C., May 5, 1897.

BY JOHN ERETY SHOEMAKER, M.D.,

OF PHILADELPHIA

Outside of a comparatively small circle of surgeons there are heard from time to time suggestions, which occasionally appear in print, that the system of "Listerism," so called, is a failure. Strange as it may seem, it is not very uncommon to hear some one say that in a given case "every antiseptic precaution" was adopted, but the result was bad. The speaker would have you believe that he had done his part and that the system was at fault.

Now, it is worth while to consider briefly where the difficulty lies; and without entering the discussion of asepsis as opposed to antiseptics

—absence of dirt versus sterilization, of dirt,—without advocating special methods or dressings, attention may be drawn to practical difficulties which lead to misunderstanding.

A few men, like Mr. Tait, vigorously attack the theory of Listerism, while they themselves carry out the principles underlying its success. The reputation of Mr. Tait, however, rests upon his operative work, and not upon his opinions or his explanations. When in characteristic style he says (*British Medical Journal*, Sept. 27, 1890, p. 728): ". . . 'The tone and attitude adopted by Sir Joseph Lister at Berlin clearly shows that the whole sad business is on its last legs,'" etc. Also (p. 729): "I venture to say that before the present generation has run out the word 'antiseptic' will be all that is left to represent this strange structure." The harm that he can do is not great among the men who are doing the best work in surgery, especially in general surgery. These cannot work for a day without discovering for themselves that their results are better or worse, according to their greater or less microscopic and chemical cleanliness in operating. Active surgeons do not care how Mr. Tait explains his good results. He might refuse to believe in the law of gravitation if he choose, but as long as he did not violate it, as long as he refrained from walking out of windows or off precipices, his opinion as to the law would make little difference. Most men care little that he denies the evil potency of germs and relies upon removing decomposable material from his wounds. They remember that he deals with a peculiar membrane and its neighborhood, that he is extremely clean in his work, and they will permit him to attack Sir Joseph Lister personally, and his impregnable principles, to his heart's content; principles of the widest practical application. The harm Mr. Tait can do is to unsettle the mind of the man who is beginning his work; and, worse than that, his writings tend to salve the conscience of those who have had no training in genuine aseptic methods, who fail consequently to fully carry them out, and who joyfully fail any champion who even seems to justify their indifference.

But even among the better trained class of men, does not one often see a lamentable failure to grasp the essential ideas of surgical cleanliness?

There are hundreds of men to-day who apparently persuade themselves that mopping a 1 to 20 carbolic acid, or 1 to 2,000 bichloride of mercury solution about a wound area constitutes using "every antiseptic precaution," as the phrase goes. There are also men who will use chemicals upon a septic patient but neglect to change infected bedding. There are men who will go to an operation with the points of their scissors, the locks and serrations of their ham-

ostatic forceps, the eyes of their needles, choked with dried blood or worse material from the last operation. They never boil an instrument. Their conscience is satisfied with the carbolic acid in the instrument pan. Some men wash their hands before an operation no better than before dinner. When an instrument or a sponge drops to the floor they may rapidly rinse it in the pan and use it at once. There are other men who have trained nurses, sterilized dressings and boiled instruments, but who, after they have washed for the operation, shake hands with a spectator, put a hand in a pocket, remove instruments from an old blood stained case, help carry a table, handle dusty bottles, or use a handkerchief, and yet *say* they use every antiseptic precaution. Many men know better. What is lacking is careful self-training and what may be called an aseptic conscience. What is wanted is a realizing sense of the real difficulty in getting things clean and then keeping them so. Carbolic acid solutions as practical sterilizers are a delusion and a snare. They work slowly at best. Unless too strong for comfortable or safe handling they do little good, and they do enormous harm by quieting the conscience of the man who ought to spend more time cleaning his hands; yet how many times do we see them relied upon when they only cover dirt. Many text-books, even the revised editions of standard works, are written from a carbolic acid standpoint. Antiseptics is a failure when it is superficial.

In a recent case of laparotomy, referred to by the author's permission, the stitches cut out and the wound opened, though it afterwards united by granulation. The operator had been cleanly, but the fault was traced to a nurse who had handled the previously sterilized silk with infected fingers. In another case the paraphernalia were elaborate and the preparations minute. The chief assistant seized a falling ether bottle, old and very dirty, and without the slightest effort to cleanse the hand again it was soon in the abdominal cavity. The patient died two days later of peritonitis, which may have been a coincidence.

A few days ago, in a hospital, a major operation was in progress. The lecturer had dilated upon the beauties of the antiseptic methods. The cat-gut ligatures proving defective, he called for silk. There was a scurrying of nurses and an ancient open box of silk was brought. A spectator with unwashed hands threw a card of silk into the instrument pan, from which a piece was taken when scarcely wet and placed on one of the largest arteries in the body. A weak link breaks a strong chain.

In a hospital case of my own, requiring careful dissection about the face, an assistant, unknown to the operator, obtained an instrument which had been used a few minutes before in opening a

suppurating bubo. In two days the wound area was an abscess under sterilized dressings.

Not long ago, in an emergency, the writer asked at a drug store for antiseptic gauze. The druggist instantly opened a beautifully decorated and labeled tin box, unrolled quite a quantity of gauze and offered it for inspection. He was, of course, told that while that might have been antiseptic gauze once it was ruined as such by his handling; a proposition which failed completely to enter his mind. No doubt that identical roll of gauze will be retailed, and the writer fears that there are physicians who would buy it measured by the yard on his counter, and yet hardly realize that it was worthless as a clean dressing or packing. But why multiply instances to show that "antiseptics," when neutralized by some single mistake, is a failure. Which should be blamed, the system or the application?

The war about asepsis as opposed to antiseptics is a minor issue. The great fact remains that the principles of cleanliness, though adopted theoretically throughout the world, are really carried out very imperfectly by most nurses, most hospital internes, some general practitioners in town and country, even (must it be said?) by many otherwise most excellent and estimable surgeons.

This is not the place to bring forward the overwhelming evidence in favor of surgical cleanliness in saving life and promoting swift recovery from operations impossible without it. This work has been done again and again. Many of us see it daily.

Let no one be misled by the war of methods into suspecting the truth of principles. Let each of us train himself constantly to make his work clean. Only by long practice can this be well done.

In regard to the use of chemicals, it is known that in abdominal operations they are not necessary. In general surgery, including railroad and machinery accidents, better results can be obtained by the use of sublimate. Perfect asepsis, though it should be aimed at, is almost impossible as a practical measure. The assistant of the moment is often untrained, and can neither be relied upon nor narrowly watched; nurses may be new to the work, derelict or incompetent; the wound is frequently infected before it is seen. The best results in general surgery are obtained with least trouble by combining the aseptic with chemical methods.

Further, let no man venture to criticize methods which he has never fairly tried; let him also bear in mind that his trial, though honest, may be superficial, and therefore faulty through his lack of patient personal training.

In conclusion then, in answer to the question: When is antiseptics or asepsis a failure? one may say, never if real, always if imperfect.

There is no doubt that the great principle of

cleanliness in surgery, whether obtained by soap, hot water, dry heat or chemicals, has come to stay, and the sooner all of us act thoroughly upon that principle, ignoring personal discussion, the better.

3727 Chestnut street.

PATHOLOGICAL ANTEFLEXION OF THE UTERUS.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY ELIZA C. MINARD, M.D.,
OF BROOKLYN, N. Y.

"Plastic operation to straighten the anteflexed uterus."

Accepting the opinion held by the most advanced gynecologists, that anteflexion is a deformity, and belongs to the group of pathological conditions which govern that order of lesion, there will be no place to discuss the old terms and divisions, which have controlled the discussions and treatment of anteflexions for a term of years past.

That this lesion is amenable to the laws and rules which govern the treatment of deformities, is self evident.

Any malformation is not usually meddled with unless it disturbs the mental or physical balance of the wearer. It must be malignant, painful, unsightly, or interfere with personal comfort or happiness.

The discovery of this deformity comes after puberty; and whether the cause is congenital non-development from malnutrition, or acquired, through inflammation, or from the result of other affections, such as adhesions, pressure or tumors, the lesion is a fact, the symptoms and suffering a certainty. The mischief is done before the case reaches the surgeon.

The points to be considered when such a case presents itself are: the amount of deformity, the complications, and the direct or indirect effect which it has or will have upon the health, circumstances and happiness of the individual.

The family physician has exhausted the mechanical modes of treatment taught by his college professor, for dysmenorrhœa, endometritis, pelvic peritonitis, diseases of the tubes and ovaries, partial stenosis and, if married, sterility. He has witnessed the failure of the drugs to relieve which are extolled so highly and which bear the trademark of our own and foreign chemists; for professors still teach that flexions are normal conditions, and are not to be considered of much account in pelvic lesions.

The gynecologist begins at the beginning, and pursues the beaten course of treatment: dilatation—rapid or slow—curetting, drainage, posterior section, with glass, rubber, or silver wire stem-

passary, intra- or extra-uterine support, and operation for imperfect invagination, without success. Months and years pass, surgeons come and go, till at last abdominal sections for diseased tubes give the science-tossed sufferer rest, if not here, in the grave.

Accepting the three forms of flexion: that of the body, the neck, and that of the body and neck, I have selected the third form to illustrate the plastic operation which I believe will work much good to suffering womanhood, and if done in time, will prevent the necessity of abdominal section in some cases. I take this because it came to me unsought, and the greater will include the lesser in most treatments.

The operation known as "a plastic operation to strengthen the uterus," by E. C. Dudley, of Chicago, which has been so clearly and ably described in the February number of the *American Journal of Obstetrics* of 1891. This case, which has proved so successful in my hands—and my first one at that—is a typical one of a severe type, taken after others had failed and hospitals refused admittance.

Mrs. M. C., aged 25 years, has been married six years without having children. She had been a stout, rosy girl before marriage, and had menstruated without pain or discomfort for three years before her marriage. Three months after marriage she began to have pains, and the flow became scanty. She was compelled to go to bed every month. Gradually she grew worse and lost flesh. She took on an anxious, scared look, though of a happy, cheerful temperament when she aroused herself. Her home surroundings were easy, and her husband kind and anxious. The desire for children and the great suffering induced her to seek treatment after six years of marital misery. She had followed treatment faithfully for six months without improvement save in general health. When she had spent her little savings, she sought treatment at my free clinic. The dysmenorrhœa had become well nigh maddening, and life had become a burden. She came to the clinic at the summer vacation, and my substitute, Dr. Mary W. Faunce, treated her for a severe pelvic peritonitis. On my return I found her quite well of the inflammation, and as I had had reasonably good success in this line of uterine lesions, I prepared to dilate. Upon careful examination I found anteflexion of the third form—flexion of body and cervix—of an acute angle, and fundus resting upon the bladder. Any attempt to pass the sound caused great pain, as the point of the sound impinged against the posterior wall of the canal. When the cervix was well pulled back only a small sized sound would pass. As it was near her monthly period, I resolved to dilate and drain. As she lived out of the city, she made arrangements to stay in town, and with the usual aseptic precautions, and under cocaine, I did rapid dilata-

tation. It was tedious work to introduce the first instrument. It was done thoroughly, and with $\frac{1}{4}$ of a grain of morphia in form of suppository; she left the office to remain in bed at a friend's home. She returned the next day looking pale and nervous. I introduced another suppository, gave her a tonic, and she left for her home. She wrote me a happy letter, saying she had passed the monthly period without pain for the first time since the third month after her marriage.

After the next period she came to my clinic, saying she had suffered more severely than before the dilatation, and she seemed so broken up that I sent her to my office from sheer pity. Before the next period I had her come into town and remain for a week. I dilated the second time, and put in an Onterbridge's silver wire stem pessary, under the same aseptic conditions and with cocaine. The stem remained three days, when uterine contractions forced it out. She remained in bed, and suffered from the stem so much as to require hypnotics and narcotics. She passed the period in bed, without pain, and a full flow, lasting three days. There was some pelvic tenderness, which passed away under treatment. She returned home, and gained in flesh and spirits. But her experience had been so unhappy that she sought hospital treatment, and wrote me to meet her at a New York hospital of note.

The physician in charge met us kindly and appointed a time for admittance. It was here, while discussing the case, that the assistant physician mentioned this plastic operation of Dr. Dudley's, and agreed to do it. When the time came for entering, an examination was made by the visiting physician, who decided that the case would be too tedious, as there was some pelvic peritonitis, and there were more urgent cases needing the bed, and she was sent home. I was thoroughly disgusted, and hoped I had been relieved of further anxiety. But she returned to me, stating that her husband had decided with her, that as I had given her the most relief, they wished I would do the operation discussed at the hospital, or any other operation I deemed proper, for her relief, as she feared she would be driven to suicide if it went on longer.

I called in consultation Dr. Faunce, who had seen her first, and described the operation I wished to do and sought her help. She entered into my views with enthusiasm, and we made ready to operate. Upon a thorough physical examination we found the left ovary and ligament quite tender, and an abdominal aneurism as complications. The heart at times was heavily overworked, but no organic lesion.

The uterus was of normal size, high up, lying over upon the bladder, and the cervix bent forward, making an acute angle. The neck measured $1\frac{1}{2}$ inch in length to the bend, which was at the internal os. There was a profuse discharge

and a severe endometritis. The sound would not pass. The anterior lip was long, the angles of flexion were immovable, and the cervix could not be straightened out. The anterior wall was thinned, and there was evidently obstructed circulation. The overburdened heart was acting in sympathy with the disturbed nervous action. The case was not an encouraging one. The *Obstetrical Journal* arrived at this junction, and Dr. Dudley's article, so ably written, was scanned with intense interest. The more we discussed and read the more we decided that this was the operation, and our enthusiasm increased. The patient aided us by her courage, and urged us not to wait over another period. The complication of the aneurism damped our ardor somewhat, but after a week's rest and treatment, we put her on the operating table, and with the usual aseptic care, etherized, dilated, curetted, washed out the cavity with solution of carbolic acid; then divided the posterior lip with scissors to the junction of the wall of the vagina with cervix, and carried the incision up to the interior os with the bistoury, then bent the cut surface upon itself and stitched the external os to the point of the cut angle near the internal os, with silkworm fibre.

We cut out a portion of the anterior lip from the external os to the vaginal wall, and enclosed the wound. The operation resembled a fine lacerated cervix which had been done in an aseptic manner. A Peasley sound entered readily, and a new canal, pointing backward, formed an entrance into the uterus at a slight curve. The uterine discharge ceased from that day.

She rallied from the ether and operation well. She did not vomit, nor was much sick. The usual toilet and diet was given. The aneurism gave some trouble and much anxiety, and was controlled by opiates. The operation gave no trouble—the stitches were removed the eighth day. The healing was good; the Peasley sound passed easily without much discomfort. She was kept in bed till after her monthly period. She was kept under observation till the second period, when she was allowed to return to her home, and a letter came before I left, stating that she was living a new life, and had had but one heart attack.

The limited time will not allow me to discuss causes and reason for operation. The author of the operation has so candidly and conservatively done this in his paper that there is no need to do so. All will receive gladly any added treatment which will lessen the suffering of the dreaded dysmenorrhea and that of sterility. I would not have the old treatment ignored. All means should be used to cure. It is as easy to do as a posterior section, adding a few minutes for stitching; and more safe with its aseptic wound than rapid dilatation. In well chosen cases it must succeed more or less, whether the indications are wholly or in part mechanical.

Whatever may be the complications, there can be no harm in making a clean, open canal for the easy flow of the menstrual fluid; to place the uterus upon a higher plane, and relieve the pressure of the rectum and the irritability of the bladder.

I will be pardoned if I am seemingly a little over enthusiastic for such relief to my suffering sex, and if I place the author of this operation—though wholly unknown to me—among the other benefactors of my sex, Sims, Emmet and Sir Spencer Wells, it is because as a physician I appreciate results.

THE RELATION OF ATMOSPHERIC CONDITIONS TO INTERMITTENT FEVER.

Read by Title, in the Section of Practice of Medicine and Physiology, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY HENRY BIXBY HEMENWAY, A.M., M.D.,
OF EVANSTON, ILL.

Among the various State Boards of Health, perhaps none have done more to raise the standard of the medical profession, and to defend the public against impostors, than that of Illinois. None has probably done more for the science of medicine than that of Michigan. What is said of the Boards, applies especially to their executive officers, who have given the distinctive character to the bodies of which they are members. Dr. Henry B. Baker's laborious care in collecting statistics, and zeal in spreading information are well known, and his work is highly valued. Like other mortals, he is liable to errors of judgment, and we fear that in such an error originated his articles on "Malaria and the Causation of Intermittent Fever," published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* (Vol. xi, p. 651, etc., and Vol. xv, p. 561, etc.), having been read before the appropriate Sections in 1888 and 1890.

The first article, coming from so high a source, commanded attention; its repetition demands the most careful investigation. If the conclusions are fallacious, the fallacies should be clearly exposed. If his reasoning is correct, the discovery is important, for it shows that the individual can easily protect himself from the disease by wearing suitable clothing, and keeping his surroundings as even as possible—keeping the house warmed by fires at night, for example. On the other hand, coming from so high an authority, by many the ideas will be regarded as facts until proved otherwise.

The articles in question do not show the judicial spirit of impartial investigation usually found

in Dr. Baker's studies, but rather show a labored, and, as Dr. Lee characterized it when the article was first read (*THE JOURNAL*, Vol. xi, p. 653), "ingenious" argument to demonstrate a pet theory. They show how unconsciously a careful student may sometimes be misled and blinded by impressions. That the results reached are consistent, neither with each other, nor with facts, we shall try to point out.

His first conclusion is that "intermittent fever is proportional, either directly or indirectly, to the average daily range of atmospheric temperature." This sounds well, but reminds one of a test for flour once given by a good lady: "Take a pinch of the flour and throw it against the wall. If it is good it will stick—or else it won't." If the proportion is sometimes direct and sometimes inverse, does it not seem that any argument based upon it lacks stability? If we grant that this double relationship is a possible cause of the fever, has the author presented sufficient proof of the existence of such a fact? The proof is in the form of tables and diagrams, which we will examine.

Figure 1 of Dr. Baker's series shows that during the late war, the number of cases of intermittent fever in the United States Army, and the average daily range of temperature, both increased up to May. In June we find a much greater rise in the curve of cases, but a fall in the daily range of temperature. In July there is a steep decline in the curve of cases, but a rise in the other line. The daily range of temperature continues to rise until, in August, it reaches its highest mark. From July the number of cases increases until September. From their highest points, both lines decline until, in December, they touch bottom. It will be seen that part of the time the lines go in the same direction, but that during much of the time the case line variations are a month behind the other. This Dr. Baker explains by saying that it is due to the accumulation of old cases.

There are two elements of fallacy in this table. Reference to figure 2 shows that the line representing the daily range of temperature in Lansing is very different from that for the average of the State of Michigan. The case line in Fig. 1 represents a wide range of country—wherever the National troops were stationed. Some were in Texas, some suffered in Florida. Many shook at Charleston, and some were taken sick in the Northern cities. If Lansing atmosphere, in the interior of the State of Michigan, is not to be taken as a basis of comparison for the State of Michigan, how much less should the sickness in the whole army be compared with the atmospheric conditions around a single building, in one corner of the battlefield.

Secondly, Fig. 1 is a partisan table. Such a study as we are now engaged in is not a control

NOTE.—For tables and diagrams 1 to 12, inclusive, see Dr. Henry B. Baker's paper on "Malaria and the Causation of Intermittent Fever," published in this journal, Vol. xi, p. 651.

and lowest points exactly corresponding with the maximum temperature, and throughout the lines do not antagonize. On the other hand, from February to March the average daily range of temperature decreases without a like change in the case line; and the daily range line reaches its climax two months earlier than the case line, and the lowest point for daily range is a month before the lowest number of cases.

In studying Michigan tables, it must be remembered that the per cent. of reports does not necessarily represent the per cent. of cases. Blanks are sent to correspondents of the State Board of Health, asking them to report simply the presence or absence of the diseases mentioned. If ninety per cent. of these correspondents have only one case each the report would be greater than if seventy of every hundred averaged five cases each and the other thirty per cent. had none. The importance of this word of caution may be seen from a study of the annual reports of the State Board of Health. They divide the State into eleven divisions, for the ten years from 1877 to 1886 the reports of intermittent fever from the upper Peninsula were only 9 per cent., while from the Northern Division of the Southern Peninsula they were 27 per cent., and from the Southwestern Division 81 per cent., and from Southeastern Division 71 per cent. In the Southeastern Division in a single month there are probably more cases of intermittent fever than during an entire year in the upper Peninsula.

From the Michigan State Board of Health Report for 1888, I compiled table and diagram 14, showing the mean monthly temperature, absolute and relative humidity, day and night ozone for a series of years, compared with the per cent. of reports of intermittent fever as given in Dr. Baker's article. It will here be noticed that the curves representing the mean temperature and absolute humidity correspond closely with the per cent. of cases. Secondly: That in the main as the per cent. of night ozone increases the per cent. of cases decreases and *vice versa*. Thirdly: The same is true of day ozone, though not so exactly. Lastly: The relative humidity does not seem to have any relationship with the per cent. of cases.

The reports for Memphis, Tenn., (table 4) strengthen the idea that the absolute temperature and not the daily range of temperature is instrumental in the production of the fever. The mean temperature and number of cases both reach their climax in July, two months after the greatest daily range of temperature. There are, moreover, decided changes in the daily range line without any appreciable effect upon the number of cases.

In Cincinnati (table 5) the climax in the daily range line comes in May. That of temperature in July, and that of cases in August. We find a

great increase in the number of cases following the spring floods. There are very great variations in the daily range line without corresponding variations in the number of cases.

The San Francisco diagram (No. 6) shows all lines reaching their highest point in September, but here again the case line follows the mean temperature more closely than the daily range. The relationship of the lines, especially from May until August, clearly shows that there is some other factor besides temperature which produces the disease.

Diagram 14. Michigan. Showing average, 1. temperature (10 years); 2. ozone day and night (10 years); 3. relative humidity (10 years); 4. grams of vapor per cubic foot of air (10 years); and 5. per cent. reports intermittent fever.

Diagrams 7 and 8 representing New York City and State, each show daily range line highest in June. Mean temperature highest in July, but the highest number of deaths from intermittent fever in September. It must be noticed that while other tables all refer to *sickness*, the data here refer to *deaths*. Since sickness must precede death we should expect the greatest number of deaths at least one month after the highest temperature, if high temperature is the cause of the disease.

Evidently the meteorological data in the State diagram are those of New York City. The daily

range is exactly the same as in the table 7, and the variation less than half a degree in the mean monthly temperature arises from the fact that for one table (No. 7) the figures are obtained by taking the reports from 1870-83, and in the other (No. 8) the reports used are from 1871-85. Believing that this did not represent the facts, New York City being about 150 miles south of the centre of the State, I prepared table and diagram No. 15, using for comparison reports for a series of years at Mohawk, which is almost exactly in the centre of the state.

In table 9 we again find the greatest daily range of temperature in May, four months before the greatest sickness, and the highest temperature in July. This table is probably the most nearly correct of any in the series which cover more than a limited area. It illustrates, however, how difficult is such a table to prepare. If we imagine ten posts placed up on the same meridian, and each one of the nine southern posts having 1000 men, while the one northern post has 6000, the mean temperature of the ten posts would not give the average temperature surrounding the men. To get the correct figures the mean of the nine southern posts must be averaged with the one northern post. Here, as in the New York tables, it is to be regretted that the Doctor did not state his authority, giving the names of the stations used.

Tables 10, 11, and 12 quite contradict Dr. Baker's previous argument and tables 10 and 11 representing India, also show that high temperature does not produce the disease. Here we find the highest temperature in May and June, the greatest daily range of temperature in February, and the least in August, but the most sickness in November.

If we suppose the daily range of temperature is equally above and below the mean temperature, we may get approximately the mean maximum and minimum temperature. This may be seen in table and diagram No. 16.

It will be noticed that in most places heretofore studied in this article malarial fever is most common at a temperature between 60° and 85° F., especially at about 70°. Neither extreme heat nor extreme cold are favorable for the disease. A glance at diagram 16 shows that until April the mercury every day went below 60°. From April to June each day it went above 95°. As soon as the minimum went above 60° the cases of sickness increased, and when the maximum came down to 87° there was a much greater increase. Every gardener knows that the young plant requires much more favorable surroundings than it does at a later period. An occasional high or

low temperature would kill the young plant while the old one might thrive. So while a temperature of 87° does not favor the development of the fever neither does it stamp out the developed disease.

Table No. 16, showing number of deaths from intermittent fever in New York State, and mean monthly range of temperature at Mohawk.

There is another potent factor not shown in these tables. In "Hirsch's Handbook of Geographical and Historical Pathology," Vol. 1, p. 257, we read: "In the malarious regions of the tropics the fevers appear as a rule at the beginning of the rainy season. They increase in extent and severity with the increasing rainfall, remitting usually at the height of the rains, especially if they be very heavy, and reappear towards their cessation or directly after the rainy season, which is, as a whole, the season when the conditions are most unfavorable to health." Again, on page 269: "The production of malaria takes place on the largest scale where the soil is constantly saturated or periodically inundated." A friend residing in Lucknow informs me that from about June 15 until September 20, it rains almost daily, but from September until June all the rain put together would not make a good Michigan shower.

¹ "Tables of Differences of Mean Temperature" in Smithsonian Contributions to Knowledge.

NOTE.—I have searched for meteorological data for India, but did not find more than generalizations. I have therefore been obliged to use the tables of Dr. Baker—his authority not stated.

Table 12, to my stupid mind, shows nothing, unless it be that the daily range of temperature has *nothing* to do with the disease. As drawn, the lines coincide in but one place, August. There are most marked changes in the daily range, without a corresponding variation in the number of cases. Not being able to obtain the mean temperature of Ft. Apache, I took that for Camp McDowell,² shown in table and diagram 17. Camp McDowell is near Ft. Apache, and practically on the same isothermal line.

Diagram No. 16. India. Showing average maximum, minimum and mean temperature, and cases of intermittent fever among native troops.

Dr. Baker's second conclusion is that "the controlling cause of intermittent fever is exposure to insidious changes, or changes to which one is unaccustomed, in the atmospheric temperature." If this is true, why is the disease so much more prevalent in hot countries than in those that are cooler? If this is true, why does not the sickness follow closely the daily range? This many of the diagrams studied show that it does not. A patient under the care of the writer since this article began, was exposed to decided

variations of atmospheric temperature. For two days she was obliged to be where the temperature was quite uniform through the twenty-four hours. She had no chill until after these two days of unusually even surroundings. This case is illustrative of many.

"The daily range (of temperature) diminishes from about lat. 40° in either direction, north or south. The precise latitude of maximum range cannot yet be given."⁴ If conclusion two is true, there would be more malaria around Philadelphia

Diagram No. 17, showing average temperature at Camp McDowell, Ariz. and daily range temperature, and cases of intermittent fever at Ft. Apache, Ariz.

than around Charleston—more in Connecticut than in Florida. Is that the fact? If so, I for one am greatly mistaken. In Michigan,⁵ the average daily range of temperature at Detroit is 15.79° ; at Kalamazoo 16.93° ; at Marquette 17.20° ; Traverse City 19.13° . If the disease is due to daily range of temperature, we should find more of the fever around Marquette than near Kalamazoo, and more near Traverse City than in Detroit. I do not understand that to be the fact.

If the daily range of temperature is an impor-

² Small variations in this case line are unimportant, on account of the small number of cases represented.

⁴ Report of State Board of Health, Michigan, 1885, p. 25.

⁵ "Tables of Differences of Mean Temperature," p. 136, Smithsonian Contributions to Knowledge.

tant element in the production of intermittent fever, why should a change of climate develop the fever? Dr. Baker says: "It is a common observation that persons who travel northward or to a colder climate, where ague is comparatively rare, not infrequently have one or more paroxysms of chills and fever soon after the change." During the war I noticed this on a large scale after movements of troops from the South.¹ Dr. Baker's explanation is not a reasonable one for me, for the reason that the temperature changes are perhaps less in the Northern than in the Southern home. In Michigan, for example, Dr. H. T. Calkins, one of the oldest practitioners in the northern part of the State, and a close observer, tells me that at Petoskey they never have malarial fever, *except in persons recently from a malarious country*. I am told the same of Mackinac. If this is true, it is a most important fact, and my own observation leads me to accept it. An individual going from Southern to Northern Michi-

The explanation of these phenomena which I have adopted, I think was first suggested by Dr. Bowditch, of Boston, though not in this exact form. The malarial poison, whether chemical or germ, acts upon the liver in such a manner as to slow the elimination of effete matter. The elimination of effete matter is accomplished through the liver, skin, kidneys and lungs. In the state of health these organs assist each other, keeping a normal balance. If an individual goes from a warm to a cold climate, the elimination through the skin and lungs is decreased. If the liver and kidneys are healthy, no harm results. If, however, as in the case of the malarial person, the liver is sluggish, it will be unable to do the work devolving upon it, and the system is poisoned with the non-eliminated effete matter. This irritates the brain and produces the chill and increase in temperature. This theory exactly agrees with my clinical experience. Antipyretics have little effect upon the disease until the liver is cleared.

gan will, unless specially protected, generally within from four to ten days show clear indications of malarial poisoning. The first symptom is not a chill, nor a fever, but a copper colored skin. The purer air causes the blood at first to flow more freely through the cutaneous capillaries, which, showing through the jaundiced skin, misleads the victim to report excess of tan. A few days later and a chill occurs, followed by a fever, and if left to itself, the disease progresses until it assumes a typhoid type. For the production of this condition I am confident that it is not necessary to bring in a typhoid fever germ.

Catharsis is not the essential factor, because compound cathartic pills and other like drugs may be given until the patient is exhausted, without any material benefit. On the other hand, if the case is seen early, calomel may be given in so small doses as to effectually clear the skin, without producing catharsis.

If a person residing in a malarious country, not being sick at the time, takes a thorough mercurial treatment before going to the North or to the sea shore, he will probably escape the usual sickness. While I would emphasize the importance of extra care as to clothing in making this change of climate, I regard the preparatory treatment as the more important. In fact, a person

¹ JOUR. AMER. MED. ASS'N Vol. xi p. 653² Loc. cit. footnote

whose liver is active will need less clothing for comfort than if his liver is sluggish. In some cases, it is necessary to continue small doses of the chloride or iodide for some time.

The usefulness of this treatment is generally known, and is admitted by Dr. Baker in conclusion seven. If, however, his theory is correct, any cathartic, decreasing the tension of the portal circulation, or heavy clothing would prevent the outbreak, as well or better.

How does a mercurial decrease the temperature? It certainly has an antipyretic influence upon a malarial fever or upon diphtheria, but it does not have any appreciable effect upon a healthy person. This effect is certainly not derived through increased heat elimination, and it must therefore be by reducing the production of heat. Since, however, it does not materially check the production of heat in a healthy person, this result must be the incidental result of the removal or neutralization of the irritating cause of the fever. If this is true the fever following a chill is not the result of non-eliminated heat being stored up, as Dr. Baker suggests. Further, if I am not mistaken, the experiments of Osler show that in intermittent fever there is increased heat production.

With regard to conclusions three and four it might be asked, how does Dr. Baker's theory explain the *cause* of delay in reaction from cold. The healthy person would react promptly; therefore this delay in reaction shows that neither the chill nor the fever represent the beginning of the disease. The mechanical effect of a chill may be a local congestion, but as soon as the cause is removed the system reacts and the only results are local primarily. If the intermittent fever is the result purely of the daily range of atmospheric temperature, since the body is daily exposed to the cold, the chill and fever would always be of the remittent type.

I am surprised to see conclusion six repeated. "In our climate those measures, such as drainage, which enable the soil to retain warmth during the night and thus reduce the daily range of temperature immediately over such soil, tend to decrease intermittent fever among residents thereon." Does drainage enable the soil to retain warmth? Almost any boy will tell you that sand in the sun is hot, but as soon as a shadow is thrown upon it it cools off. The rich black loam heats slowly and cools slowly. Dry climates are those most subject to great range of temperature. In northwestern Texas the traveler may suffer extremely from the heat by day, but at night he covers himself with a thick blanket and places a little water in a saucer from which he skims a thin layer of ice in the morning. In India we have already seen that there is the

greatest range of daily temperature when the ground is dry. Dr. Chas. Denison took the records of 25 dry and 25 moist climates and obtained therefrom the mean daily range of temperature for four classes of places as follows:

1. Extreme dryness, 36.51° Fahr.
2. Moderate dryness, 20.63°
3. Moderate moisture, 17.09°
4. Extreme moisture, 13.61° Fahr.

On the contrary, then, drainage increases the daily range of temperature, and so if Dr. Baker's theory is correct it ought to favor the production of intermittent fever.

On page 417 of the Report of the Michigan State Board of Health for 1880, I found the following report from one of the correspondents of the board. "During the first half of the month (August) the moisture in the air was as abundant and the temperature so uniformly high, that unhusked corn in the shock, also corn in the corn cribs began to grow vigorously. During the third week of the month malarial diseases rapidly arose, which I think was partially due to the prolonged uniform heat and moisture. There was also one half less azone during the first half than during the last half of the month." This report is for Washington, in the southeast part of the State. From the same report, pages 317, 321, 326, 344, and 349, I get the mean temperature, absolute humidity, day and night ozone at Washington, and mean daily range of temperature at Detroit as follows (having no like data for Washington).

TABLE 18.

MONTH	TEMPERATURE.		ABSOLUTE HUMIDITY.	OZONE.	
	MEAN.	DAILY RANGE.		NIGHT.	DAY.
June	61.21	18.43	5.21	2.42	2.22
July	72.47	18.54	6.31	1.21	2.66
August	78.51	18.74	8.17	0.85	1.65
Annual Mean	69.44	16.60	7.01	3.67	2.97

It will be noticed that during these three months of summer the thermometer kept constantly within the range we have before found the most favorable for the production of malaria. While the daily range of temperature was higher than the average it was not as great as in May (22.48°).

A monograph by Dr. G. H. Wilson, of Meriden, Conn., member of the State Board of Health, published several years ago, gives an account of the progress in a definite direction from southwest to northeast, of intermittent fever. This seems to be strong evidence that the disease is due to a specific poison or germ.

From clinical evidence and meteorological investigations therefore it appears:

1. That intermittent fever is due to a specific germ.

ordinarily prescribe two cathartic doses of calomel combined with opium, the first to be taken a week before starting, and the second three days after.

Transactions of Ninth International Medical Congress, Vol. 8, p. 37.
Grams of vapor in cubic foot of air. Average for 9 months. No report for January, February and March.

2. That the development of this germ, and hence the production of the fever is favored by a moist atmosphere ranging in temperature between 60° and 85° F.

3. That the germ is taken into the body by inhalation or through drinking water.

4. That the fever is the result of irritation of the heat producing centre of the cerebrum. This irritation is perhaps partially due to the direct effect of the specific germ, but it is also due to the retention in the circulation of effete matter.

5. That under favorable conditions the true malarial fever may assume the character of a genuine typhoid fever, without the agency of a typhoid germ.

6. Exposure to an average temperature below that to which the person is accustomed, may develop a latent malarial condition, but exposure to cold does not produce the disease.

7. There being no definite and constant relationship between intermittent fever and the daily range of atmospheric temperature, we must conclude that daily variations in atmospheric temperature are not essential for the production of the disease.

Ozone is a potent germicide. It seems to the writer that its influence upon the disease is incidental and negative. When ozone is abundant it attacks the germs in the air and deprives them of their virulency. There is less ozone over swamps than in the open fields; less in the winds filtered through the underbrush, than in the same winds before reaching the woods. There is more malaria on the windward than on the lee side of a swamp. Conditions favorable to the growth of malaria are therefore destructive of ozone.

That the presence of ozone in the atmosphere does not greatly increase the power of the human organism to withstand the effects of the germ. I am led to think from the fact that a person going from a malarious region, where the amount of ozone is small, to a colder region, where the amount of ozone is greater, is almost sure to have strong signs of malarial poisoning soon after arrival.¹

The occurrence of the fever at high altitudes and in cold weather are sometimes mentioned as arguments against the paludal theory of the etiology of the disease. Let me simply hint at an explanation. One day after clambering up the crags on the coast north of Larne, Ireland, I was surprised to find myself in a bog while still close to the edge of the high cliff. Again: the upper plateau of Mackinac Island is 295 feet above

the water's edge, and yet there one may find marshy ground.

The heating of the house in winter draws air from the cellar. The air of the house is not so rich in oxygen as that out of doors. One may therefore find in the house in winter the necessary heat, moisture, and decaying vegetation—all the atmospheric conditions known to be essential.

MEDICAL PROGRESS.

MODE OF ENTRY OF THE TUBERCULAR POISON INTO THE BODY.—A very good summary of the various paths of infection adopted by the tubercle bacillus is given by C. BOLLINGER in the *Münchener Med. Wochenschrift*, 1890, No. 43. He considers that the frequency of infection through the skin has been under-estimated. Several cases have been recorded of direct inoculation by wounds received from broken spittoons, etc., by bites, after circumcision, by morphia syringes, and earrings. Eczema and impetigo increase the susceptibility of the skin. No case has as yet been attributed to vaccination, and it would appear that the tubercle bacilli are unable to live in the vaccine lymph. They also appear unable to pierce the pores of the skin as do some of the pyogenic organisms. The susceptibility of the mucous membrane is increased by inflammatory processes, such as otitis, rhinitis, conjunctivitis, pharyngitis, etc.; from thence the poison travels to the submaxillary glands and those of the neck, and generally causes local tuberculosis of the glands. The chief point of infection is of course the lungs. Local predisposition is best exhibited by apices which have been before diseased, but have undergone a healing process. The movement is deficient both in expiration and inspiration, and the liability to reinfection is increased by anemia, irritants such as coal and metallic dust, constitutional influences, such as diabetes, disturbances of digestion, and unhealthy surroundings. The poison may pass through the lungs and attack the bronchial glands, under which circumstances the disease may be very insidious. The predisposition of the lungs again exhibits itself in metastasis: not every tubercular disease of these organs is due to inhalation of the bacilli or their spores. As regards primary tuberculosis of the testicles, joints, and bones, Bollinger considers that a latent hæmatogenic infection must be understood, which leaves as little trace of its point of entry as does a primary septic endocarditis or an osteomyelitis. Tubercular disease of the larynx depends upon an autoinfection through the sputum. The rarity of this disease in children is explained by the infrequency of pulmonary cavities in the rapid forms of phthisis.

¹ Dr. Baker calls attention to the fact that persons exposed to night air over low lands are more liable to the disease than if they are exposed only through the day. It is suggestive that, according to Table 14, in Michigan, the months showing the most intermittent fever also show less night than day ozone, but generally there is more night than day ozone. Does light have any influence on the growth of the germ?

Primary tuberculosis of the intestine generally, combined with an affection of the mesenteric and retro peritoneal glands, is usually occasioned by means of vitiated food and contaminated feeding utensils. Secondary tuberculosis of the intestine depends upon an autoinfection. The tubercular poison passes through to the intestine unaltered by the juices of the stomach and attacks the Peyer's patches and solitary follicles. Tuberculosis of the peritoneum, which is three or four times as common in men as in women, can arise directly from ulcers of the intestine, from tubercular abdominal glands, or, especially in women, from the urogenital tract; further, through contagion from the lungs and pleura, and finally in the course of miliary tuberculosis, or from caseous bronchial glands. Primary tuberculosis of the peritoneum is rare (3 to 4 per cent. of all cases). As regards the infection from milk, this is, in Bollinger's opinion, undoubtedly due to the udder of the cow being affected with the disease. Infection through the milk of tuberculous women has not yet been proved. In tabular form the organs of the body are thus affected, beginning with those most frequently diseased: 1, lungs, 2, the lymphatic glands, 3, intestine, 4, serous membranes, 5, larynx, 6, spleen, 7, joints, 8, bones, 9, liver, 10, kidneys, 11, the genital tract, 12, the skin, 13, the brain and spinal cord, 14, muscles.—*The Lancet*.

EHRlich's TEST IN TYPHOID FEVER.—This test, which has been known for a number of years, has till recently been regarded by many rather as a medical curiosity than as of diagnostic value. DR. C. E. SIMON, of the Johns Hopkins Hospital, has recently shown that by carefully following the precise directions for its use, valuable information may be derived. The test consists of two solutions. 1. A saturated solution of sulphanilic acid in five-per-cent. hydrochloric acid, and 2. A five-per-cent. solution of sodium nitrate. These are to be mixed, just before use, in the proportion of 40 cc. of (1) to 1 cc. of (2). If this mixture be added to urine from a case of typhoid fever, the further addition of ammonia will produce a play of colors varying from an eosine rose to a deep garnet red. The best method of applying the test is to take a few centimetres of urine in a test-tube, adding an equal quantity of the sulphanilic acid mixture and shaking thoroughly; 1 cc. of ammonia is then run carefully down the side of the tube. At the junction of the two liquids there will be observed a ring of the characteristic color, which is produced in scarcely any other disease than typhoid fever. Dr. Simon's conclusions may be thus summarized: 1. The reaction may be obtained in typhoid fever from the fifth to the twenty-second day of the disease. 2. Its absence from the fifth to the ninth day indicates a very mild

attack, save in children, although this rule is not an absolute one. 3. As it occurs previous to the appearance of the rash, it is a very useful aid in the diagnosis of typhoid fever.—*Therapeutic Gazette*.

CARDINAL POINTS IN BACTERIOLOGY.—*The Bacteriological World* says:

The words germ, bacteria, microbe, schizomycetes are used in our present literature almost as synonymous terms, but microbe seems preferable to germ or bacteria, and schizomycetes is a better scientific term than either.

That these are unicellular, and assimilate nourishment, seemingly by absorption in the media in which they live, but they must transform (alter) the foods found proper, and yet unfit in nature, for their use and appropriation.

Bacteria living on dead matter encounter no living resistance, whilst those feeding on living tissues, or fluids in living tissues, meet the living cells of the body and have to combat them.

The diastases secreted by the various beings, whether highly organized, or unicellular and microscopic, have something in common as to their respective objects, and their properties of transforming matter.

The rôle of microbes in the world is complex and necessary, though some are injurious. They act as scavengers; return to the air and water the organizable elements abstracted daily by the vegetables of the globe, and indirectly by animals, and indispensable to life.

The bacteria that invade living organisms which happen to be fit for their nourishment and growth, are in a sense parasites just as much as the tapeworm is.

Spontaneous generation of living organisms, no matter how little, is a fallacy.

EFFECTS OF STRYCHNINE ON THE STOMACH.—The effect of nitrate of strychnine on the functional activity of the stomach has been recently made the subject of a careful research by Dr. Gamper, of St. Petersburg, who employed for the purpose of his experiments four healthy young hospital assistants. He found that strychnine increased the amount of gastric juice secreted, the general acidity, and the quantity of free acid in the secretion. It also hastened the absorption from the stomach, and strengthened the mechanical movements. Its effect, too, continued for some time after its administration had been stopped. Like many other Russian observers, Dr. Gamper seems to have been highly impressed by the value of strychnine in chronic alcoholism, declaring that it is the most effective of all drugs in such cases. The thesis contains a long list of references to the literature of stomach affections, published in six or seven languages during the last ten years.

MEDICINE IN JAPAN.

The progressive spirit of the Japanese people—and particularly in the direction of medicine—has of late been abundantly shown to Mr. Ernest Hart, editor of our justly distinguished contemporary across the seas, the *British Medical Journal*.

Mr. Hart has been temporarily sojourning in the land of æstheticism and flowers, and he finds very much to praise, but little to criticise, and an opportunity for suggestion, which, if wisely cultivated, may prove no less meritorious and successful in Japan than has maintained under the sterner régime of the Anglo saxon.

In the way of gratification and commendation the observer found the emergence of the nation as a unit from a vast superstitious thralldom of a not greatly-distant past; the rapid acceptance and appreciation of Science in its wonderful onward march; the newer systems of government; the improved architecture; and the advanced provisions in learning.

Upon the latter condition, it may be said—the advanced provisions in general learning—the former manifestly and entirely depend. They are simply results, sequences, as, indeed, has been the case the world over.

The Imperial University, with departments of law, medicine, engineering, literature and science, each thoroughly equipped, and especially—as trite to a medical mind—the department of medicine with a faculty of no less than fifty-five professors and assistant professors, many of

whom had attained distinction in foreign countries previous to taking upon themselves the responsibilities of leading onward the minds of their countrymen, very much impressed the Englishman.

A light criticism rested upon the system of training nurses; upon bathing facilities in hospitals; and upon the general care and comfort of hospital patients, all of which was offered in the most friendly spirit.

Then as to suggestions, which were in the line of a national medical association, and a beneficent organization possibly in connection therewith.

The value of such creations were exhibited by a clear statement of the organization, objects, method, and condition of the British Medical Association; together with a rehearsal of what the British Medical Association had accomplished, and the position, usefulness, benefits, and general scope of the *British Medical Journal*. Also the insurance feature which has been so well planned and carried out under the patronage of the Association during the past few years.

Then, with a candor equal to that taken while in the attitude of representative, critic and teacher, the English physician craved knowledge from his hearers, the strange new people—a knowledge which he all but admitted could only come from them, however high a degree of scientific skill, or prolonged a research might be required for its development.

Among the questions the profession in Japan is asked to decide are these, viz., the etiology and communicability of leprosy; the pathology and prevention of beri-beri; the influence of prolonged lactation upon the mother's health, upon infant mortality, and the rate of increase of population; the comparative immunity of the Japanese from scarlet fever, and the rarity of its spread; the nature of senile (?) gangrene so commonly found in middle age in Japan; the influence of the customary hot baths, particularly in infantile pneumonia; the apparent unimportance of hæmorrhages in typhoid fever; and the real place of massage as a therapeutic measure.

Many of these are very pertinent inquiries, and if the Japanese physicians, working under the encouragement offered by the royalty, and the stimulus which comes from the earnest watchfulness and waiting of a great race, can effect a reasona-

ble solution to any or all of them, then will the finer genius of the amalgamation of minds moulded, it may be, by irrelative race characteristics, become more patent.

Mr. Hart said in his address before the Medical Faculty of Tokio: "These are among the subjects on which we should be pleased to offer you the hospitality of our medical periodicals, and as to which we should be glad to receive communications at the meetings of our British Medical Association."

To this desire for a broader interchange of thought, to this wish for a closer union of scientific minds whose objects remain the same despite the vast distance which divides, and the different blood—commonly speaking—which gives its nourishment, the profession in America may earnestly unite.

It is really a little surprising that the Japanese mind has so quickly reacted to the impulse of learning, and is to-day so far advanced as to provoke not alone the plaudits of the more pretensions, but to create an appeal to her scientific possibilities; and although digging into the depths of recondite medicine is not at all confined by national margins, and should not be, yet inasmuch as the eyes of the medical world have pointed eagerly towards England, towards France, towards America, and lately towards Germany, it is not without the limits of probability that we may all yet look with like eagerness in the direction of promising Japan.

HIGHER MEDICAL EDUCATION.

The promotion of all efforts to advance and raise the standard of medical education is always a vital subject with those who have at heart the best interests of our profession. And it is with a sense of gratification that we note from year to year a visible improvement in the standard adopted and approved by the leading educators of our country.

An encouraging feature at this time is the effort that is being made to affiliate and more or less directly connect the best medical schools with established universities.

This works advantageously to all such institutions; it enables students in the academic course to so arrange their studies as to make the last two years in the latter count as the first two in their more strictly professional studies.

A young man who has pursued his studies in this manner has much the advantage of those who enter a medical college with an indifferent preparation. In fact the one represents the trained roadster, that easily skips along and reaches the goal in good condition. While his fellow, of equally good blood and breeding, that that has had little or no grooming, stumbles over the slightest obstacle, shies at imaginary hindrances, indifferently obeys the guiding lines, frets, sweats, and is a good deal blown at the wind up on the home stretch.

The following circular issued by the Illinois State Board of Health sets forth the situation of this subject, and very properly solicits the aid of practical teachers in making up a science course that can be adopted as a standard:

ILLINOIS STATE BOARD OF HEALTH, OFFICE OF THE SECRETARY.

SPRINGFIELD, June 6, 1891.

Dear Sir:—There is a demand, from medical teachers and young men that intend to study medicine, for a literary course preparatory to the study of medicine. This demand has been met by a few of the literary institutions in the United States, and it is hoped and believed that it will be much more generally met during the next two years. The following institutions now offer science courses for students that intend to study medicine, or that intend to teach or otherwise engage in biological work: 1. University of Wisconsin; 2. University of Pennsylvania; 3. Johns Hopkins University; 4. University of Notre Dame; 5. Yale University; 6. Cornell University; 7. Princeton University; 8. Lake Forest University; 9. Northwestern University; 10. West Virginia University; 11. University of Kansas.

As must be obvious, such a course should be based on biology, and should include thorough work in this science, as well as in osteology, comparative anatomy and chemistry, with English, French, German, some Latin, clay modeling, free-hand drawing, mineralogy, mathematics through trigonometry, mechanics, logic, general and pharmaceutical botany, and in the last year psychology.

It is of course understood that botany, being a branch of biology, should have a prominent place in the course.

The catalogues of the universities mentioned contain the list of studies offered in their science courses.

Such a course should extend over four years. This will involve no loss nor waste of time to the student. The Illinois State Board of Health now requires that students of medicine matriculating in the autumn of 1891 or thereafter must study medicine four years and must attend three courses of lectures,—no two in the same twelve-month, in order to obtain a license to practice in Illinois. This rule will apply also in some other States. The Illinois State Board will, however, recognize a thorough course in science, such as indicated above, as equivalent to two years' study and one course of lectures, thus enabling the student to enter the second class in the medical college. This makes the full time of study six years in the literary and medical schools, or two years less than is required of the student pursuing a strictly classical course. Not only will time be thus saved, but the science student will be much better prepared to enter the second course of the medical school than will the classical student to enter the first year.

The Illinois State Board wishes to make up a science course that can be recommended to any college wishing

to adopt such a course, and having but little time to study the subject, I desire to enlist your aid and have your advice in the matter so as to make the course as practical and as beneficial as possible. Will your faculty, therefore, make out such a course as it thinks best for the purpose, and send it to the Secretary of the Board?

The demand from medical teachers and from students of medicine having been met by some universities, must be met by all that would continue to hold a high rank as educators of young men for the work of life. Such a course is also the best preparation for the study of veterinary science. Respectfully,

JOHN H. RAUCH, M.D., Sec'y.

SOCIETY PROCEEDINGS.

New York Academy of Medicine.

SECTION ON ORTHOPEDIC SURGERY.

Stated Meeting, May 15, 1891.

SAMUEL KETCH, M.D., CHAIRMAN.

DR. T. HALSTED MYERS presented a case of marked rickets, called congenital on the mother's positive assertion that the greatly enlarged epiphyses of the tibiae, femora, and radii were present when she first examined the child a few days after birth. The sternum at that time, she noted, also was abnormally prominent. She had been in very good health all through gestation, and the father was a healthy man. No specific history could be obtained.

At present, the child is six years of age, and presents all the deformities of rickets in a marked degree, except that the head is well shaped, and there is a marked increase of the normal dorsal curve of the spine, rather than the dorso-lumbar kyphosis usually found in these cases. An unusual degree of permanent knee and hip flexion also exists, and the patient assumes, when resting, the hand-to-knee position of Pott's disease. The epiphyseal tenderness present seemed to indicate an active stage of the disease. After being nursed nine months, the child had a mixed diet, not especially starchy, nor lacking in animal fats.

THE CHAIRMAN thought it not improbable that the spinal symptoms were the result of an acute lesion occurring coincidentally with this diathesis. In cases of simple kyphosis which he had examined, one of the points in the differential diagnosis had been the absence of psoas contraction, and in most of these cases the curve, unlike this one, disappeared when the patient was in the prone position.

DR. JOHN RIDLON exhibited the photograph of a patient, nineteen years old, who had had exactly this position all his life. There were additional curves in both the tibiae and femora, which had developed gradually during his growth. It was worthy of note that psoas contraction was also present in his case.

DR. NEWTON M. SHAFFER had seen psoas contraction in these cases of rachitis. The case just presented was not, in his opinion, one of tubercular disease of the spine, but a sensitive condition of the cancellous structure in the bodies of the vertebrae which simulates Pott's disease. He had never seen a case which he could consider one of congenital rachitis, and he was inclined to look upon this one as an instance of rachitis acquired at a very early age. It was not uncommon to find in rachitic patients a condition of the muscles somewhat resembling that found in tubercular joints. He was reminded of a case which he had seen in St. Luke's Hospital, in which there was a very sensitive joint, associated with muscular symptoms which might suggest hip-joint disease, but these were simply due to hyperemia of the epiphysis occurring in a rachitic subject, and in due time, with proper attention to nutrition, these symptoms disappeared.

DR. RIDLON said that he had expected to present a patient illustrating certain peculiar conditions found in persons who had the caisson disease. His patient had been working in compressed air for sixteen years, and during the past year, had had forty or more attacks of the cramps which are peculiar to this disease. Associated with these were stiffness, gradual shortening, and outward rotation of the right lower extremity, with a direct upward dislocation of the hip for a distance of three-quarters of an inch. This man had informed him that he knew of a number of others who had been working in compressed air, who had paralysis with shortening of the limb.

THE CHAIRMAN said that he had seen a man, 40 years of age, who had been a caisson worker and diver, and who presented an affection of both hips. There was very little motion except in abduction. There was no history of rheumatism, or other constitutional disorder.

DR. SHAFFER had recently seen at the Orthopedic Dispensary a caisson worker, who presented bilateral hip symptoms, and who was scarcely able to walk. In this case, the symptoms were those of a pronounced rheumatic type, and the changes were apparently due to rheumatic arthritis.

DR. RIDLON also exhibited photographs of the latest modification of Grattan's osteoclast, and of some of the cases which this surgeon had treated by means of the instrument. He now used it for forcibly correcting club-feet, and in the opinion of the speaker, it was the handiest and most efficient contrivance of its class that he had seen.

NON-UNION AFTER OSTECTOMY IN A CASE OF SEVERE RACHITIS.

THE CHAIRMAN presented a little girl with a very exaggerated form of rickets, whose symptoms indicated that the disease was still active.

The chief point of interest was the fact that about three years before, a skillful surgeon had performed osteotomy upon her for the correction of a severe form of bow-legs, and this had resulted in non-union. This case showed the folly of operating in the presence of such a virulent form of rachitis. The treatment in his hands had consisted in the application of a coaptation splint, and of a perineal crutch, which by means of a snap joint allowed motion at the knee, but prevented dangerous traumatism, and favored locomotion. The idea of the apparatus was to favor locomotion rather than to attempt to secure union.

DR. ROYAL WHITMAN doubted if this treatment would lead to union of the fragments, for the end of the bones in such cases become extremely hard, and usually require to be removed before union can be secured.

DR. R. H. SAYRE thought the non-union in this case might have resulted from the fact that the deformity was so great, that in order to correct it, a considerable interval must have been left between the ends of the bone after the osteotomy.

(To be concluded.)

DOMESTIC CORRESPONDENCE.

LETTER FROM BALTIMORE.

Judged by numbers, the late session of the medical schools of this city was a great success. The following was the attendance and the number of graduates:

SCHOOLS	MEDICAL MATRICU- LATES.	MEDICAL GRADU- ATES.
College of Physicians and Surgeons	About,	110
University of Maryland	25	85
Baltimore Medical College	125	81
Baltimore University	55	32
Woman's Medical College	22	6
Total	527	294

The attendance has been equally good at the dental schools. The Baltimore College of Dental Surgery having about 226 students and 77 graduates, and the Dental Department of the University of Maryland about 163 and 64 respectively. The Maryland College of Pharmacy had about 125 students and 29 graduates. So that the total number of students and graduates in medical and allied schools in this medical centre (not including the biological and preliminary medical at the Johns Hopkins University and the post-graduate at the Johns Hopkins Hospital) is about 1,366 of the former and 457 of the latter, figures the size of which I suppose few outsiders would suspect.

The Maryland College of Pharmacy has just celebrated the semi-centennial anniversary of its foundation. Its lectures were at first delivered at the University of Maryland, which set apart quarters for its accommodation. Besides the commencement and commemoration meeting of the college, the exercises included a magnificent re-

ception with music and lunch at the college building, and a banquet at night. There were visitors from New York, Philadelphia and other cities. The college is now in a very prosperous condition, has a large new building, well equipped, and has a high reputation for honest and faithful work in training young men for the pharmaceutical profession.

The College of Physicians and Surgeons introduced a novelty at their commencement this year, which has elicited criticisms both favorable and the reverse. It was the adoption for the graduates of the English cap and gown. The effect was very pretty, and the manifest advantages of having a cheap and uniform attire cannot be questioned. The college furnished the suits, charging a nominal sum for their use by the students. There does not appear to have been any difficulty or opposition to the adoption of the innovation. An attempt was made last winter to introduce the custom at the Hopkins, but it met with little favor, only President Gilman appearing in cap and gown at the anniversary exercises February 22.

Miss Mary Garrett has given another evidence of her liberality and interest in the higher education of her sex by offering to contribute an additional \$10,000 to the endowment fund of the proposed Johns Hopkins Medical School. In a letter dated April 27, addressed to President Dobbin, of the Board of Trustees, she makes this offer payable October 1, 1892, subject to the following conditions: That by February 1, 1892, the trustees raise the remainder of the sum necessary to bring the endowment up to \$500,000—the minimum limit proposed by the trustees—and further that the trustees shall give notice in February, 1892, that they will open the school in October, 1892, and shall actually open it then. The committee of ladies organized to raise \$100,000, having accomplished their object, has disbanded. The following represents the present status of this endowment: The entire sum raised by the committees of ladies of Baltimore and elsewhere and paid over to the trustees May 1 was \$111,000; there were already in hand additional funds sufficient to raise this amount to \$178,780. In order to avail of Miss Garrett's offer, it is therefore necessary to raise \$221,219. The trustees have accepted her offer and have resolved to endeavor to raise the balance required. There is no doubt that her interest is so great that she will extend the required time should it be necessary to do so. Of the \$111,300 raised by the ladies, Baltimore contributed \$68,882; the next largest contribution Boston's \$20,231, and Philadelphia's \$8,075.

Dr. George F. H. Nuttall, of San Francisco, a graduate of the University of Göttingen, has been appointed to the vacancy in the bacteriological and hygienic department at the Johns Hopkins Hospital, occasioned by the acceptance by Dr. Alexander C. Abbott of the directorship of the new Hygienic Institute of the University of Pennsylvania.

The death of Dr. John Frederick May, of Washington, recalls the fact that in early life he held the Chair of Surgery in the Trustees' Faculty of the University of Maryland, at the time when that school was split into two schools (1837-39).

The Sisters of Mercy are erecting a four-story addition to the City Hospital, connected with the College of Physicians and Surgeons, for the use of their colored patients, at a cost of \$20,000.

Dr. James Carey Thomas, one of the Trustees of the Johns Hopkins University and Hospital, has gone to Europe, and one of the chief objects of his journey is stated to be to examine into the structure and architecture of European medical schools, with the purpose of utilizing the information in the construction of the Hopkins school.

The use of the Koch lymph is gradually falling into desuetude here as elsewhere. There never was much gush over it here, and its use at the Hopkins was confined to lupus and incipient cases of pulmonary tuberculosis. A judicious skepticism and timidity characterized the attitude of our physicians towards it from the start, and consequently we have had no deaths or bad results to report. The results as a whole have been disappointing, and although a few cases are still under treatment, the probabilities are that ere long it will become a matter of the past.

The death of Judge George W. Dobban, at his country seat near Baltimore, on the 28th of May, at the age of 81, has removed from our midst one of our most distinguished and public-spirited citizens, and one who has been very active in the cause of education. Among the positions he held at the time of his death were Regent of the University of Maryland and Dean of its Law School, Trustee of the Peabody Institute and of the Johns Hopkins University and Hospital. From 1867 to 1882 he held office as Judge of the Supreme Bench of Baltimore, and for many years had been President of the Board of Trustees of the Johns Hopkins University. He was a most courteous gentleman with a cultivated mind and scientific tastes, and he enjoyed the respect, veneration and love of the entire community.

Another death which is deeply felt among us is that of Dr. Richard Gundry, the able specialist on insanity and superintendent of our State insane asylum, which took place from Bright's disease, on April 23. He was a native of England and 60 years old. He took charge of the asylum here in 1878, having held similar positions previously in Ohio. He was also Professor of Materia Medica and Mental Diseases in the College of Physicians and Surgeons of Baltimore since 1882. He was an enlightened physician, a man of scholarly attainments and high professional standing.

Professor Wm. C. Jarvis, of the University of New York, delivered the annual address before the Alumni Association of the University of Maryland, on April 1st, the subject being "Glimpses of Metropolitan Life."

A very successful concert in the interest of the University of Maryland Hospitals was held on April 10, under the auspices of the ladies connected with the Faculty of that institution. The object was to raise a fund for the increase of free beds, the hospitals being without endowment. Vladimir de Pachman, the pianist, was the chief attraction, and the entertainment was a great success, nearly \$2,000 being cleared. The chief hospital of the University (formerly known as the Baltimore Infir-

mary) is one of the oldest standing hospitals in the country, having been erected and opened in 1824, and being entirely under the control of the Faculty, and immediately adjoining the University building. It has by its clinical advantages enabled the institution to take a high rank among the medical schools of America.

The ninety-third annual meeting of the Medical and Chirurgical Faculty of Maryland was held April 28-30, under the Presidency of Professor Thos. A. Ashby, who delivered a stirring address on the need of better professional organization in Maryland. The paper of the meeting was undoubtedly that of Professor Wm. H. Welch on the "Caustion of Diphtheria." It has since been published in full in the *Medical News*, and should be read by every one who wishes the latest information on this disease from a master hand. In honoring Prof. Welch with the Presidency of the Society for the ensuing year, the Faculty has conferred still greater honor upon itself.

Dr. Randolph Winslow, Professor of Surgery in the Woman's Medical College here, has been elected to the chair of Anatomy and Clinical Surgery in the University of Maryland, in which he was formerly Demonstrator. Dr. I. K. Trimble has been elected Professor of Anatomy in the Woman's Medical College, vice Prof. Jay, transferred to the chair of Practice of Surgery. There are rumors of approaching changes in the *personnel* of the Johns Hopkins medical staff. It is announced that the organization of the "Southern Homoeopathic Medical College" of this city has been perfected by the election of a Professor of Surgery from Washington, and that the lectures will begin in October next in a rented building. When the Hopkins opens in 1892 we will have seven medical schools here!

It is to be hoped that the action of the American Medical College Association in Washington, in reaffirming by a large majority its determination to exact a preliminary Latin requirement, will settle that matter for the future with the medical schools of the country, and that those who voted for it and against reconsideration were sincere in their action. The only two schools here that did so were the University of Maryland and the Baltimore University. The former institution is making ready for the institution of the three year graded course in the fall by the institution of histological and chemical laboratories. It has not been announced yet who will take charge of the former.

I send you the following compositions on George Washington, which are veritable curiosities in the way of preliminary accomplishment, showing as well as anything could the need of some standard at least of requirements in those who undertake the study of medicine. They were handed in by two candidates for matriculation in one of our medical colleges, *one of whom had been a teacher of a public school*. I am glad to say both were rejected.

1. "George Washington When a boy could not tell a boy could not tell a lie he cut one of his fathers Chury trees with his hatchet when Father called him and aske who cut the tree he said I cut it with my hatchet he became a man of zeal and industry was beloved by all who

knew him he fought many battels and by his cunning defeated Napoleon he married became the first President of the United States lived to a good old age. Oct 1st."

H. "General Washington was born in Virginia he was a truthfull Boy a good Chresttian a noble man in war & in peace he was the first President of the United States of America he was and considered the fathar of our country By his bravery who are a free and independent people to think and act as whe think Best he was honest in all his ways."

I give them as near literally as I can. Yours truly,

E. F. C.

LETTER FROM PHILADELPHIA.

(FROM OUR OWN CORRESPONDENT.)

Although la grippe, influenza, dengue, horse distemper, "it," the great unknown, or by whatever name it may be known to future medical historians, has not favored Philadelphia this spring with such obvious marks of attention as it has some other cities of the Atlantic sea-board, yet this may be explained by the fact that it committed such ravages a year ago that the susceptible material was largely exhausted. However, we have had sufficient number of these cases to supply clinicians with abundant material for study. In addition to typical cases of the disease, which are comparatively few this year, there are large numbers of abortive cases, showing the poison is still with us, and is responsible for a large amount of general ill health and lowered vitality in the community. In one respect this epidemic differs from epidemics of dengue. The late Prof. Samuel H. Dickson, formerly of Charleston, Va., noticed the fact that dengue was self-protective and that persons who had an attack would not be liable to suffer at the next appearance of the epidemic. Quite a number of persons who had influenza last year have it again this year although, it is true, as the rule, in a milder form. In the treatment, quinine seems of little use and only adds to the patient's discomfort. Antipyrin, acetanilide, sulphonal and other agents of the aromatic group, can only be used cautiously, if at all, on account of the tendency to lower the action of the heart, but where the pyrexia is marked, salicylic acid or phenacetin in small doses (gr. iii, vi) given every hour or two, is decidedly useful. Small doses of Dover's powder, with a little camphor, or of the compound morphine powder for restlessness; ice to the head if there is headache; small pieces of ice swallowed when there is nausea, and a dose of calomel with jalap or rhubarb, for constipation, are often followed by marked relief. In addition to this, a good elixir of coca (Lorini) or the well-known Mariani wine or caffeine citrate will be generally needed to support the weak heart, and nervous system. During convalescence, ignatia or nuxvomica should be an appropriate remedy; but patients seem very susceptible to strychnine and some complain of cramps and muscular pains. The hypophosphites with iron, form a good tonic, but the best restorative after all is a change of air to the mountains or seashore, with nourishing food given only in moderate quantity and at regular times. The above brief outline of treatment has proved uniformly

successful in the experience of the writer, who has had no deaths and few complications. In delicate nervous cases it contributes very much to their comfort to dispense with linen sheets and to substitute woolen ones, or just put the patients between blankets.

A movement is on foot to increase the endowment of the Medical Department of the University of Pennsylvania. The Trustees have accepted the offer of the Faculty to contribute \$100,000, and of the Provost, Dr. Pepper, to give \$500,000, towards a fund for additional endowment of Medical Department of \$250,000, and will lengthen the term to four years when the fund is made up; it is expected to be raised within five years. It is possible that this fund will be raised and that the University will be placed in a position to extend the course in medicine so as not to fall behind in the race with Harvard and Johns Hopkins. The death of Prof. Joseph Leidy was a severe loss to the school and to the community; but the Board of Trustees seem in no hurry to fill the vacancy. The prospects at present are that the Chair will be divided into surgical anatomy, for which Dr. John B. Deaver is an eligible candidate; and historical anatomy which may be offered to Dr. Harrison Allen, who was formerly Professor of Physiology in this institution and resigned.

At a meeting held June 2, 1891, the following appointments were made: Dr. George A. Piersoll was elected to the Chair of Human Anatomy, Dr. Harrison Allen to that of Comparative Anatomy, J. P. Grover Griffith, Prof. of Diseases of Children, in place of H. A. Hare, resigned. Dr. Edward Martin was elected Professor of Genito-Urinary Diseases, John D. Deaver was made Assistant Professor of Applied Anatomy.

The Jefferson Medical College has lost within a short time two of its most distinguished professors: Prof. Bartholow and J. M. DaCosta. The place of the former was promptly filled by the election of Dr. H. A. Hare; that of the latter is still vacant. Drs. J. C. Wilson, Frederick P. Henry, both of Philadelphia, and Jas. T. Whittaker of Cincinnati and several others, have been discussed as candidates, but the issue is uncertain. The Medico-Chirurgical College also has a vacant chair, Dr. Wm. T. Waugh, Prof. of Practice of Medicine, having resigned. It is understood that he is not without hope of a transfer to the identical chair at Jefferson.

There is a prospect that the state of Pennsylvania will give the Medico Chirurgical Hospital \$70,000, to enlarge its buildings; the legislature has passed the bill which only awaits the signature of the Governor.

The medical societies of this city keep up their scientific work manfully in spite of the influenza and unfavorable weather. At the College of Physicians' meeting last week (June 3), Dr. Oscar H. Alis read a paper on Fracture of the Condyles of the Humerus treated by Extension—with a suit for malpractice and a verdict for the defendant, who was C. E. Kurts of Bellaire, Ohio. The last meeting of the County Medical Society was enlivened by a tilt between the operating gynecologists, lead by Joseph Price, and the disciples of Apostoli, and his electrical treatment for uterine growths, of which Dr. Betton Massey is an able exponent. The conflict has been going on for several years but the ardor of the contestants

seems to be increasing rather than abating; to outsiders it is quite entertaining.

The Society of the State of Pennsylvania, during the past week, (June 2, 3, 4 and 5, has been holding its forty-first annual session in the city of Reading, about sixty miles from Philadelphia, in the coal and iron region. It was not as largely attended as usual. The principal addresses were that of the President, Dr. Allen Craig, of Columbia; that on Medicine, J. Chris. Lange, of Allegheny City; on Mental Disorders, Samuel Ayers, of Pittsburg; on Ophthalmology by J. A. Lippincott, of Pittsburg, and on Obstetrics by J. Milton Duff, also of Pittsburg.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The recent annual meeting (its seventh) of the Fifth District Branch of the New York State Medical Association was one of the best attended and most attractive that it has yet held, and its varied scientific proceedings were of a high order. The President, Dr. Stephen Smith, took for the subject of his address "Opium in the Treatment of Acute Peritonitis," and it was devoted principally to a detailed and graphic account of the introduction into Bellevue Hospital, by the late Prof. Alonzo Clark, of the opium treatment of puerperal peritonitis. In the course of it he quoted the following passage from Dr. Clark's description of the outbreak of puerperal fever at Bellevue in the year 1851. "In three or four days seven cases were sent me from the lying-in wards. One was returned for error in diagnosis, and six put under treatment. Having proved that prudence was so much more conspicuous in any house physician than courage, another house officer, who combined them both, was selected to be in almost constant attendance. The instructions were in these words: 'I want you to narcotize those women within an inch of their lives.' He did it, and saved every one of them. This gentleman is now known over the whole land as a learned and distinguished surgeon. I feel called upon to give his name in this connection, that he may be a witness to the facts I state, and for the admiration with which his nerve and prudence impressed me." Dr. Smith said that notwithstanding this assertion Professor Clark failed to give the name of the surgeon referred to, but as he himself was then a resident student at Bellevue Hospital, and had charge of the six cases mentioned, he assumed that he was the person meant, and would take this occasion to witness to the facts recorded.

Up to this time mortality from puerperal fever at Bellevue had been appalling. Of 21 cases reported by Dr. Vache, the resident physician in 1840, 10, or nearly 50 per cent., proved fatal. This death rate, he said, was not unusual at that period, and the treatment was so mixed that it was difficult to draw any conclusions as to the efficiency, or rather inefficiency, of any one remedy. Still it was noticeable that in 17 of the 21 cases purgatives were actively employed, and that in twelve of these calomel and turpentine, two approved antiseptic agents, were administered freely.

Up to the time when the opium treatment was adopted, as Professor Clark remarks, "peritonitis was a fearful word, a large proportion of those attacked by it died of it." Dr. Smith described in detail the treatment of the six cases placed under his charge by Professor Clark, who gave the most particular directions as to their care. At the outset each patient received 1 gr. of opium, or its equivalent, every hour for three doses. No effect being perceptible, the dose was increased to 2 grs. every hour, and continued for three doses. Failing with this dosage, the opium was increased to 3 grs. every hour. In short, he was especially charged not to be governed by the amount administered, but by the effects produced. In four cases the last mentioned dose had the desired effect and the opium was continued in that quantity. In one of the remaining cases it had to be increased to 4 grs. every hour, and in the other to 12 grs. every hour. This case proved an anomaly in tolerance of opiates. During twelve days the patient took the equivalent of 1,450 grs. of opium, and yet at no time was she so narcotized that she could not be roused by a touch on her wrist.

The recovery of these six consecutive cases naturally produced a profound impression, and as the cases were typical of those ordinarily occurring in Bellevue, and as opiates were the sole remedies employed, it was apparent that a new era in the treatment of this affection had begun. From this time forward opium continued for twenty years to be the chief remedy used in peritonitis in this hospital, and with satisfactory results. Opium in peritonitis came into use generally in the city of New York, and Professor Clark stated that in private practice the drug had been, perhaps, more curative than in the hospital. Happily, in these latter days, said Dr. Smith, antisepticism had greatly diminished the frequency of this formidable disease, especially the puerperal form, and in the meantime the remedial measures had been greatly increased. One of the most important results of recent investigations was the differentiation of the types of peritonitis caused by various agencies; and as there were many types of this affection, having their causation in various conditions (some being of microbic and others of non-microbic origin), it was as yet by no means certain where the line was to be drawn between the medical and surgical treatment. Whatever might be the possibilities of the art of surgery in the treatment of peritonitis, the question, he thought, might be pertinently asked, Has any remedy or combination of remedies in the hands of the physician given results equal to or better than opium, in a series of cases similar to those recorded in this paper? And if it be true that by employing opium, as recommended by Professor Clark, more than 50 per cent. of cases of peritonitis, as met with in practice, can be saved, should not this method of treatment be at once adopted in all cases, and the resources of surgery be applied when the manifestations of the disease indicate the necessity of its additional remedial measures?

An interesting discussion followed the address, but it was greatly regretted that Dr. A. Palmer Dudley, who had been announced to read a paper on "Cathartics in the Treatment of Acute Peritonitis," failed to make his

appearance. In the course of the discussion Dr. H. L. Carroll remarked that it was noticeable that the advocacy of saline cathartics in peritonitis came, as a rule, from the abdominal surgeons, such as Lawson Tait, for instance; and Dr. T. H. Manley, in referring to the discussion on the management of peritonitis in the Surgical Section of the American Medical Association, at its Newport meeting, spoke of the extreme opposition with which everything in the way of palliative treatment was met on that occasion. For his own part, he said, his experience had led him to regard the opening of the peritoneal cavity as a more serious matter than many seemed to regard it, and it was his belief that in the next ten years there would be fewer laparotomies performed for the relief of inflammatory conditions than had been the case during the past ten years. So much interest was manifested in the subject that, at the suggestion of Dr. Gouley, it was determined to request that at the general meeting of the State Association in October next, a discussion on the treatment of peritonitis, to be opened by a paper from the President, Dr. Smith, should be arranged for.

(To be concluded.)

P. R. P.

"M.D., Indianapolis."

To the Editor:—During the past few weeks a case was brought up in the courts of this city which induced very free remarks relative to the requisite standing of a man in the States to possess the title M.D. S. E. L. Smith, of this town, was registered as a licentiate of the Society of Apothecaries, which gave him rights to practice. But said Smith assumed the title of "M.D., Indianapolis," and he was summoned into court, fined the maximum fee of \$100, with probably a quarter as much costs. Mr. Smith produced in court, during the trial, a document which gave him the title of "M.D., Indianapolis." It was said to have cost him \$30. The medical man who prosecuted the case said that such a title could only be one of those foreign or American titles which could be got for a dollar or two.

It might be well for the young men of the States to know something of this "*§30 M.D., Indianapolis*" mill. We especially recommend it to the proud men in the city of that name. Mr. Smith was prosecuted and fined because he *assumed* the title of Medical Doctor (M.D.). The titles M.D., etc., said the prosecutor, enable the public to distinguish between qualified and unqualified practitioners. The assumption of a title would mislead the public. We are sorry to hear of the "bogus diploma" again, and thought it died a natural death in Philadelphia. It chagrins a medical man of the States to listen to the English courts ridicule our medical titles as being worth "a dollar or two." But we cannot help thinking that we deserve it to some extent. A student in England studies five years of about eight months a year to get his title. I know scores of medical men in the States who got their title in two winters' study of five months each. Certainly we cannot expect very high regard from a European court toward titles so easily acquired. It is an unconsoling argument to say that the American student is such a genius that he can learn as

much in two winters as a European can in five years. There is but one way out of the matter, and that is to lengthen the course of study, and prosecute the bogus diploma man. Respectfully,

FRED BYRON ROBINSON.

Birmingham, Eng., May 26, 1891.

MISCELLANY.

AN INTERNATIONAL MEDICAL CONGRESS.—The managers of the National Prohibition Park, of Staten Island, invite representative medical men from all localities in the United States and Canada to meet in conference on the 15th and 16th of July next, in the great Auditorium Building of the Park. The chief object of the meeting is to be the comparison of views on the relationship of physiology and alcohol. Among the questions to be discussed will be the following:

What are the Hereditary Effects of Drunkenness?
Are there any Hereditary Effects that Follow Moderate Drinking?

To what Diseases are Inebriates More Especially Exposed?

Is Alcohol a Poison?

Is Alcohol in Any Sense a Food?

What are the Proper Uses of Alcohol as a Medicine?

Is there Danger of Producing the Drink Habit from the Prescribing of Alcoholic Medicines?

How Large a Percentage of Deaths May be Attributed, Directly or Indirectly, to the Use of Strong Drink?

Should Alcoholic Liquors ever be Used Except under the Direction of a Medical Adviser?

At this Conference, all views will be given an impartial hearing. No restraint will be placed upon the discussion save that of the time limit. Many well-known medical men have already signified their willingness to participate in such a conference. No harm, but much good, may come from this conference of views by leading physicians.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from May 30, 1891, to June 5, 1891.

Capt. Jefferson R. Kean, Asst. Surgeon, is granted leave of absence for one month, to take effect after the return of Major Robert H. White, Surgeon, to duty at Ft. Myer, Va. Par. 1, S. O. 125, A. G. O., May 29, 1891.

Major David L. Huntington, Surgeon, is granted leave of absence for three months, to take effect on or about June 15, 1891. With approval of the Secretary of War. Par. 2, S. O. 124, A. G. O., June 1, 1891.

Capt. Edward C. Carter, Asst. Surgeon, will proceed without delay to Ft. Canby, Washington, and report to the commanding officer for temporary duty, relieving Major John D. Hall, Surgeon, who will proceed to Ft. Sherman, for duty as Post Surgeon. Par. 1, S. O. 71, Dept. of the Columbia, May 22, 1891.

Capt. Henry F. Birmingham, Asst. Surgeon, extension of leave of absence on account of sickness granted in S. O. 108, May 12, 1891, from this office, is further extended to June 21, 1891, on surgeon's certificate of disability. By direction of the Secretary of War. Par. 6, S. O. 126, A. G. O., June 2, 1891.

Major John D. Hall, par. 1, S. O. 74, Dept. of the Columbia, May 22, 1891, transferring him from Ft. Canby, Washington, to Ft. Sherman, Idaho, is confirmed. By direction of the Secretary of War. Par. 1, S. O. 126, A. G. O., June 3, 1891.

Capt. Van R. Hoff, Asst. Surgeon, is relieved from duty as a member of the board of medical officers to which he was assigned by par. 6, S. O. 78, April 7, 1891, from this office, and will, upon the completion of the duties assigned him by par. 6, S. O. 116, May 14, 1891, return to his proper station, Ft. Riley, Kan. By direction of the Secretary of War. Par. 11, S. O. 126, A. G. O., June 3, 1891.

Capt. Jefferson R. Kean, Asst. Surgeon, is assigned to temporary duty at Ft. Myer, Va., until the return of Major Robert H. White, Surgeon, to duty at that post. By direction of the Secretary of War. Par. 8, S. O. 122, A. G. O., May 28, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending June 5, 1891.

Surgeon C. V. Gravatt, detached from Naval Hospital, Yokohama, Japan, and ordered home.
Surgeon Franklin Rogers, detached from special duty, Norfolk, Va., and to Yokohama Hospital.

ORIGINAL ARTICLES.

PRACTICAL EXPERIENCE IN THE TREATMENT OF ACCIDENTAL ABORTION.

*Read in the Section of Obstetrics and Diseases of Women, at the
Forty-second Annual Meeting of the American Medical Association,
held at Washington, D.C., May, 1891.*

BY BEDFORD BROWN, M.D.,

OF ALEXANDRIA, VA.

EX-PRESIDENT OF THE MEDICAL SOCIETY OF VIRGINIA; MEMBER OF
THE MEDICAL EXAMINING BOARD OF VIRGINIA; MEMBER OF
THE SOUTHERN SURGICAL AND GYNECOLOGICAL
ASSOCIATION.

The facts and statements presented in this paper are based exclusively on the personal observation of some two hundred or more cases of accidental abortion which occurred at various times during the past forty two years of my professional life. And I have endeavored to make it as practical in character as possible. It has been my custom of late years, when first called to attend a case of threatened abortion, accompanied with uterine pain and indications of hæmorrhage, in the beginning to give a hypodermic of $\frac{1}{4}$ gr. of morphia, $\frac{1}{8}$ of atropia, and, if there is much depression from hæmorrhage, $\frac{1}{16}$ gr. of strychnia, and 20 minims of the fluid ext. of ergot. This quantity of ergot is just enough to constrict the arterioles without stimulating contraction of the uterine vessels. In two or three hours this practice may be repeated, if found necessary, and will aid materially in arresting the progress of abortion.

The fact may be recalled here that the causes of this accident are of a varied and complex nature, and of course require, to a certain extent, a modification in our preventive treatment suitable to the peculiar nature of the existing cause. Take a given number of cases of abortion, and we will find in one that it is simply and purely of the nature of a neurosis, having its cause in unusual mental or nervous excitement acting on the contractile fibres of the uterus. At other times it is eminently reflex in its character, the current of nervous action being reflected from some other organ on the cord, and thence on the uterus; while in other cases still it is due to temporary increase of blood pressure, the result of over-exertion, sudden injury, high fever. When pure-

ly of a neurotic origin, the uterine contractions begin previous to signs of hæmorrhage. But when from increase of blood pressure, the hæmorrhagic symptoms usher in the case. Then again, it may be due to a variety of blood poisons acting on the nutrition and growth of the placenta and cord, and also on the fatus, as the infection of syphilis, of typhoid fever and scarlatina. My next procedure, as a preventive measure, is to cause the vagina to be thoroughly douched with water at a temperature of 110° , containing 1 gr. of permanganate of potash to the oz. And then, if hæmorrhage be present, to order a vaginal douche of a pint of hot water containing 1 or $1\frac{1}{2}$ oz. of pulverized alum to the pint of water. This very active astringent causes prompt contraction of the os, and forms a firm clot, which fills the cervix and arrests bleeding without the necessity of a tampon, which is objectionable at this stage. The viburnum and kindred remedies I use, but have found uncertain. In my personal experience of all methods for the prevention of abortion, rest, absolute and continuous, is the most valuable. Rest of mind and body in the recumbent position, without ever assuming the erect or semi erect attitude for a single moment, for any purpose whatever, has accomplished more, in my hands, than any other single method. With absolute rest, and one of the bromides in 10 or 20 gr. doses three times daily, as the bromide of lithia, and if nervous or circulatory excitement are present, 2 drops of the tincture of aconite root, many imminent cases may be averted. The bromide of lithia and aconite give a quietude of mind and body that predisposes the patient to a state of composure and comfort, and not only renders her less amenable to existing influences, but subdues undue arterial pressure, and nervous erethism, and enables her to bear confinement with more philosophy and less irritation. While copious hæmorrhage in the early stages of abortion is exceedingly dangerous to the life of the fatus, I have yet to witness a fatal case to the mother, and I have seen repeatedly instances where the patient was blanched, cold, and for a time pulseless. Yet, under proper restoratives, they would react. But I have seen fatal cases, the result of septicaemia from retention of placenta, before the introduction of our

admirable modern antiseptic methods. For the arrest of the genuine neurotic contractions of the uterus without hæmorrhage, the chloral enema, composed of 5ss and 20 grs. of bromide of potash, three times a day, exerts the most potent effect on the lower spinal cord and the reflex pelvic nerves, of any other remedies in my knowledge.

There comes a period in the progress of abortion when it becomes dangerous longer to tamper with preventives, and when it even becomes desirable to complete that process as speedily as possible. The use and application of the tampon at this stage are questions of infinite importance and delicacy. It will save the mother, but as surely condemn the fœtus to death. Its primary action is to arrest hæmorrhage, and its secondary is to put the whole process of abortion through its various stages to completion, as a rule, promptly and speedily. Otherwise, in this stage, it can do no harm, and is a power for good. But when applied in retained placenta with hæmorrhage, it is not unattended with danger. It will seal up a decomposing placenta in a cavity at a temperature of 100°, and conduce in every way to the generation of active septic poison, which may be serious, or it may be mild, but nevertheless it will generally be developed. I have never applied a tampon for hæmorrhage in retained placenta for twenty-four hours, that it was not followed by more or less septic fever, and occasionally pelvic peritonitis or salpingitis. The type of fever may be exceedingly mild and the local inflammation exceedingly limited, the area not covering more than a square inch. But there is usually a rise of temperature and acceleration of pulse. But occasionally they are of a more serious character. In my experience, this mild form of septic fever has so often followed the sealing up of an offensive, putrid placenta, that I always anticipate it.

In the first stage of abortion, previous to the expulsion of the fœtus, for the tampon to prove efficient, the vagina should be thoroughly washed out with a warm solution of permanganate of potash 2 grs. to the oz. The patient is then laid across the bed near the edge, in the lithotomy position, and a large bivalve speculum introduced, through which balls of cotton or iodoform gauze as large as walnuts, with small cords tied around their middle, which are permitted to protrude from the vagina. These pellets are pressed up with dressing forceps against and around the os uteri in the roof of the vagina firmly, until that canal is firmly packed with the pledgets, and then a soft catheter is inserted into the urethra. The attending physician may now leave his patient, and rest assured that there will be no further hæmorrhage until their removal, and that the patient will be preserved in an aseptic state for twelve hours.

A tampon well timed and executed is a blessing to both physician and patient. But one ill timed,

badly prepared and inefficiently applied, is a curse to all concerned. In my judgment, the tampon cannot be properly applied without the use of the speculum, and in my experience, the best form for this purpose is the large bivalve. With this instrument no assistant is needed, as with that of Simons. I have repeatedly been called in the dead hours of night to cases of abortion with alarming hæmorrhage, and after placing the patient in position, inserted my bivalve, and with my iodoform gauze pledgets packed the roof of the vagina around and over the os, then filled up the vagina firmly with pledgets of absorbent cotton, gave a hypodermic of morphia, atropia and strychnia, and returned to my bed, with perfect confidence that in the morning I would find my patient in a satisfactory state, and in all probability a fœtus and secundines, partially or wholly expelled, in the vagina. But in the event that the os uteri is contracted, the fœtus in a dead condition, and is retained and gives rise to exhausting hæmorrhages, what is the proper course of procedure in this condition? Ergot alone, in this state of affairs, only causes increased contractions of the os, without facilitating the expulsion. The method which I have adopted of late years, in cases of this kind, is to dilate the os and cervical canal with an antiseptic cotton wool or iodoform gauze tampon, wrapped in a conical form around a metal instrument in the form of a conical screw, and inserted by a rotary motion until the os is dilated to the extent of 1 inch or 1½ inch in diameter, and permitted to remain while 5ij or more of Squibbs' fl. ext. of ergot is injected by enema into the rectum. The ergot acts very powerfully on the muscular fibres of the body of the uterus, while the fibres of the cervix and os remain in an inert condition because of the presence of the dilator, and the fœtus and secundines are usually promptly and easily expelled through the expanded os. The ergot, given in this way, with 5 grs. of quinine internally, acts on the cord and muscular fibres of the uterus with great promptness and force. The rotary dilators which I use were prepared, at my suggestion, some ten years ago, by the Messrs. Ziemssen, and when associated either with carbated or iodoform vaseline, the absorbent cotton or gauze is wrapped around in the form of a cone, and gradually inserted by turning the instrument to the right. When this is completed, the instrument is simply turned to the left, and the threads of the screw gradually likerate it and permit the tampon to remain. The advantages of this method are that the body of the uterus is, as a rule, except in adherent placenta, enabled to expel the contents entire.

In a certain proportion of cases of abortion, after expulsion of the fœtus, the placenta, either detached or adherent, is retained *in utero*. I think that the profession will bear me out in the asser-

tion that the retained placenta in abortion gives rise to more evil consequences to the patient, and more anxiety and annoyance to the attendant, than any other feature in its management. In truth, the pathology of the retained placenta is the pivotal point, largely, on which the favorable or unfavorable prognosis will depend. We can, in a certain proportion of cases, prevent the occurrence of abortion. If not, we can, as a rule, promptly expel the fetus. But when the secundines are retained or adherent, we have a more complex case, that may entail a long line of evils in the form of hæmorrhages, septicæmia, inflammation, as pelvic peritonitis, phlebitis, salpingitis and metritis. The ideal method, in my judgment, in the delivery of the retained secundines, is to discard all instruments, as hooks, forceps and curettes, and to rely upon the hand and its prehensile extremities, and an occasional dilator. To attain proficiency and success with the fingers in these cases, certain preliminary and coöperative arrangements are necessary. In the first place, the patient must be placed on the back across the bed, with the pelvis on the edge, and the limbs drawn up as in the position for turning. An intelligent assistant must press the womb well down in the pelvic cavity and keep it there, and the os can usually be brought within 1½ inch of the vulva. If the os is rigid and contracted, nothing can be accomplished without the use of an anæsthetic, and the greater my experience increases, the more I am convinced that these cases justify the employment of anæsthesia, and the more I am convinced, also, of the importance of the prompt and early removal of the retained secundines. With all mental and physical resistance at an end, the soft and dilatable vagina and os uteri can be invaded with the fingers, and the hand if necessary, with impunity, and the operation completed without difficulty. This operation should be preceded by the permanganate douche, and the hands of the attendant washed in a sublimate solution. When the secundines have been successfully removed, there is an end of the trouble. As previously stated, the tampon retained, pressure placenta is dangerous, though it will arrest hæmorrhage. I have in times past seen a sealed up placenta, from the use of the tampon, keep up hæmorrhage and septic fever for weeks, when all of this could have been avoided by its prompt removal. Then I am satisfied that adherent placenta is a frequent occurrence in the early months of pregnancy, which cannot well be removed by instruments. In certain cases, particularly after the second month, the fingers cannot well reach the cavity of the uterus without the entire hand being introduced into the vagina. When necessary, I never hesitate to do this, and find that it can be accomplished with perfect ease and impunity to the patient. Then we have entire command of the situation, and the retained

placenta can be easily removed. Or, if it should be adherent, it can be peeled off and raked out without difficulty. The sensitive and intelligent fingers are the best, the safest, the most efficient curette in our profession. And I am convinced that the entire process of curetting the uterus with the fingers, while the patient is under chloroform, is far less dangerous than the use of instruments. Up to the fourth month, with the uterus pressed low down into the pelvic cavity, the hand in the vagina and the fingers *in utero*, the secundines can be removed without much difficulty. But subsequent to this stage—that is, after the fourth month, this method of procedure is not practicable. Then it becomes a very grave question for consideration, whether the entire hand can be introduced with perfect safety and ease into the cavity of the uterus for the removal of the retained or adherent placenta. This is an interesting and important question. On a number of occasions I have introduced the hand, disinfected, into the uterus at the fourth month or after, for the removal of retained or adherent placenta, with the patient under chloroform, with perfect ease and safety, and successfully, without any ill consequences. I have never introduced it at an earlier period than this, though it is possible that it could be accomplished in multiparæ at an earlier period.

For the purpose of more clearly illustrating the statements made in relation to the treatment of retained placenta, I will cite the following cases:

Case 1.—Mrs. T., a young married woman, aborted with her first child at the fourth month. The dead fetus was expelled, but the secundines were retained, and there was no hæmorrhage following the expulsion. The umbilical cord was found in an atrophied condition. Various methods were resorted to for the expulsion of the placenta, but without effect. The patient was then placed under chloroform, laid across the bed in the position for turning, with limbs drawn up, and my assistant directed to press the uterus down forcibly in the pelvis, and my right hand, after disinfection with sublimate, introduced into the vagina and then into the relaxed uterus with perfect ease. I was surprised to ascertain with what ease and rapidity this operation could be performed at the fourth month, and how thoroughly relaxed were both the vagina and uterus. The placenta was found to be entirely adherent, which accounted for the absence of hæmorrhage. It was cautiously peeled off and raked out of the cavity with the hand. The patient suffered for ten days with slight septic fever, which yielded to antiseptic treatment. In twelve months from this time this woman became pregnant again, and aborted at four and one-half months. The dead fetus, with an atrophied cord, was expelled, and the secundines retained as in the previous case. I had no hesitation now in resorting promptly to

the same treatment as in the first instance. The placenta was again found adherent and effectually removed. The patient also had a similar attack of septic fever, but of less duration. As an important part of the history of this case, it should be stated here that this woman, soon after marriage, contracted syphilis from her husband, for which I treated her in the primary stage before pregnancy. The infection had undoubtedly lingered in the system, and was the cause of adherent placenta, atrophy of the cord and abortion. Subsequently I treated this patient for several months, until she became pregnant a third time, by means of iodide of potassium and bichloride of mercury. This pregnancy went to the full term, when she was delivered of a healthy child. There had been no signs of quickening.

Case 2.—Mrs. M., a young married woman, contracted syphilis from her husband soon after marriage. She was treated for this, it was supposed successfully. She became pregnant in twelve months, and aborted at the end of the fourth month. The fetus was still born, and the placenta was retained. After resorting to the usual methods of removing the afterbirth, I was unsuccessful, and then placed the patient under chloroform, directed the nurse to press the womb down into the cavity of the pelvis, and, the woman being in the proper position across the bed, the hand, after disinfection, was with perfect facility and impunity introduced into the uterus, and the placenta, which was adherent, removed without difficulty. The practice has been inculcated by many high authorities that the secundines can be left in the uterus before the second month, there to be decomposed and escape in a disintegrated state with perfect safety. I regard this as erroneous in theory and practice. And while it is true that, in a certain proportion of cases, nature seems to resist infection, there are others in which the results are deplorable. I have had a small adherent placenta of six weeks old give me infinite trouble for many weeks and months, from hemorrhage, irritation, septic infection and sub-involution. In my experience, the earlier the retained placenta is removed the better. If, in these cases, I am not certain that every shred of secundines is removed, and the slightest trouble recurs, I swab the cavity of the uterus out every day or two with carbolic acid and tincture of iodine, and wash the vagina out with the permanganate solution. To indicate what disastrous results may follow the neglect of this rule, I will cite the following case:

Mrs. E., a married woman, had a miscarriage at the sixth week in her fourth pregnancy. She had retention of the afterbirth and but little hemorrhage. When seen some two days subsequently she had had a chill, followed by fever. There was pain and tenderness in the right inguinal region, and very soon extensive phlebitis, then ex-

tensive oedema of the limb, then erysipelas of the thigh, and suspension of circulation in the foot with symptoms of incipient gangrene, followed by death from septicæmia—all originating from retention of a small placenta only six weeks old. In certain cases I have pursued a still different course in the delivery of the placenta. In the past six years two very remarkable cases of retained placenta, accompanied with extensive and dangerous concealed hemorrhage, have come under my observation and care, one of which was reported at the time in the *Virginia Medical Monthly*, the history of which I will present on this occasion:

Case 3.—Mrs. S., a married woman, became pregnant with her second child, and while in a country neighborhood, aborted at the third month. The attendant supposed the entire contents had been expelled, and for a period of two weeks subsequently there was no trouble. Then the abdomen began to enlarge rather rapidly, while there was no discharge whatever from the vagina, which enlargement was accompanied with pain and soreness of the abdominal parietes. Just at this time the health and strength of the woman began to decline in a marked manner. She came to our city, and I was called hurriedly to see her. I found a woman completely exsanguined, cold and almost pulseless, and suffering great abdominal pain. There were all the general indications of excessive loss of blood, but no discharge from the vagina or intestines. The uterus was about the size of that of a woman at her sixth month of pregnancy. After learning the history of her previous condition, I was convinced in my own mind that I had a case of dangerous concealed hemorrhage to deal with, and that it required prompt and efficient measures to save my patient. In the first place, a hypodermic of $\frac{1}{4}$ gr. of morphia, $\frac{1}{5}$ gr. of atropia and strychnia was administered. Then the os uteri, which was closely contracted, was dilated with a conical tampon of iodoform gauze well coated with carbolated vaseline, inserted on the rotary dilator, and permitted to remain while 5ij of fluid extract of ergot was administered by enema per rectum, and the vagina washed out with permanganate solution. In thirty minutes active uterine contractions began, and in an hour from commencement of treatment there was expelled more than a half gallon of tough, whitish-colored, fibrinous concretions, and a large quantity of coagulated blood, when the uterus was rapidly reduced to its small dimensions. In this mass of fibrinous concretions and coagula a three months old placenta and cord were found embedded, in a perfect state of preservation. This patient gradually regained her usual health under treatment.

A paper on the treatment of abortion would hardly be complete without allusion to the management of the collapse so often arising from

hemorrhage in the progress of that affection. The onset of collapse, in its suddenness and degree, depends largely on the rapidity with which blood is withdrawn from the circulation, and the inability of the heart and arteries to accommodate their calibre to the sudden diminution of the circulatory volume. To meet this new condition of affairs we have two leading objects before us: one is to maintain and even increase the contractility of the heart and arteries, so as to establish this accommodation which is lost, and thereby prevent that paresis of the vaso motor system which is present in all cases of fatal collapse, but also to increase the circulating volume by adding new serum in sufficient quantity to make up, in part, for the deficiency. On a moment's reflection in the treatment of collapse, we will observe that most of our general remedies are such as are addressed to the vaso-motor system, and partake of the nature of stimulants of that system. Morphine, atropia, strychnia internally or hypodermically, and nitro-glycerine internally, constitute some of our most potent agents for sustaining vaso motor action, and for the prevention of paresis of the heart. And these agents do meet the emergencies of the case better than any other in our profession. A heart and artery whose contractility cannot be excited by agents are certainly dead to all other stimulants, including alcohol. But to coöperate fully with the action of these vaso-motor stimulants, it is of the utmost importance to increase, if possible, the circulating volume of blood by adding to its aqueous constituents. This I have been enabled to accomplish without much difficulty. My custom now, in the treatment of all forms of collapse in abortion, in cholera morbus, post-partum or hemorrhage from any cause, is to have injected into the rectum a pint of beef-tea, or if not convenient, a similar quantity of warm water. Then, by means of a hypodermic syringe containing an ounce, hot water at 105° or 110° is injected under the skin twelve or fifteen times, which is equal to another pint. A quart of warm fluid thus suddenly added to the general circulation, exerts an astonishing effect in the process of restoration. To this warm water I add a small quantity of chloride of sodium and bicarbonate of soda. In certain cases of collapse where these methods have been put into execution, it has been exceedingly interesting, during the progress of reaction, to observe the increased arterial pressure and of cardiac action, the return of warmth to the surface, the increased power of nervous action, the return of consciousness and interest in life and surrounding objects, the disappearance of pallor and emaciation, and that contraction of the features in extreme cases of this kind. In the treatment of collapse from hemorrhage, it is needless to continue in our efforts by powerful stimulation to lash an exhausted heart to increased action,

when there is comparatively nothing for it to act upon. But if we will but give this jaded heart something substantial to act upon, we will see how promptly it will respond to stimulants.

In calculating the dangers and advantages of the respective methods of treating retained placenta in abortion, namely: the expectant, by which nature is left unaided; the use of instruments, or its removal by manipulation with the fingers, an experience covering some three hundred cases, during a professional life of forty-two years, sustains me in the opinion that the latter is the safest, easiest, and the most effectual of all methods. And I have found that anesthesia adds greatly to the facility of these operations, and in truth is a necessity to success and very greatly increases the security of the patient's life and health. In a majority of cases of retained placenta, anesthesia is not only necessary to complete the operation of removal, but the neglect of its influence has often led to imperfect and incomplete operations that have practically defeated the object.

With thorough anesthesia we have absolute command of the situation, without in any way adding to its dangers. Without the influence of anesthesia there is danger of lacerating the rigid os uteri. With it the os and cervix are thoroughly relaxed, and in no danger of laceration. It is equally true of the perineum. A perineum and vagina that will yield only to two fingers, under anesthesia affords no resistance to the entire hand. And a womb contracted as hard as a ball, fully under chloroform becomes a soft, relaxed, unresisting bag to the hand when inserted.

It is certainly our duty to prevent abortion if possible. If not possible, then it is equally our duty to bring it to a conclusion in the speediest and safest manner possible. Hypodermics of morphia or opiates internally have not, in my experience, accomplished much to arrest the uterine pains of abortion, nor has ergot done much to control hemorrhage. Thirty grs. of chloral by enema and 20 grs. of bromide of lithia, with a teaspoonful of fl. ext. of viburnum prunifolium every two or three hours, will allay this spasmodic action better than opiates. This, in connection with absolute rest of mind and body in the recumbent position, without the patient's ever assuming the erect or semi-erect position for a moment, constitute the most effectual preventives in my knowledge of the act of abortion. In alluding to the positive advantages of rest of mind and body, and quietude of the nervous system, in prevention of abortion, I recall the history of a case which occurred some seventeen years ago. This young woman, in the third month of her second pregnancy, had frequent and severe uterine pains and repeated hemorrhages for some four weeks. She during this time had numerous enemata of 30 grs. of chloral

after failure of opium, and 20 grs. of bromide of lithia every four or five hours, with absolute rest of mind and body in the recumbent position. The fœtus was not only retained until the full term, but was healthy and vigorous at birth, and is now a healthy young man.

CAN THE GYNECOLOGIST AID THE ALIENIST IN INSTITUTIONS FOR THE INSANE?

*Read in the Section of Obstetrics and Diseases of Women, at the
Forty-second Annual Meeting of the American Medical Association,
held at Washington, D. C., May 1897.*

BY I. S. STONE, M.D.,
OF WASHINGTON, D. C.

This question should receive an affirmative answer without debate. There are, however, many who refuse to be convinced of the necessity for special treatment of the various ailments to which the insane are subject, claiming as they generally do, that the local or peripheral cause, or factor, must yield if at all, to such treatment as may influence directly the central lesion. The question is asked by the gynecologist briefly thus: Are there not in every community of from one hundred to five hundred, many cases of uterine or pelvic disease? Is it not true that in a community of five hundred sick women, sick mentally often because of bodily infirmity, that the statement should be doubly true? This statement is made *ex cathedra*. But taking the words of various alienists, besides the proof offered by the gynecologists, there is a place for gynecology right here. We wish to note in the beginning of this paper, that, as many are insane from any cause influencing and reducing the standard of health, the appropriate treatment of the special organ involved may have as good proportionate result, in the insane as in the sane. It is not necessary to question the ability of a specialist to detect disease in his department, however much difference there may be as to treatment. Taking these suggestions as a basis for investigating the question at issue, let us see what the alienists have to say first. Bucknill and Luke recognize ovarian insanity, and say such form is commonly associated with ovarian and sometimes uterine diseases. Dr. Bucknill says: "There can be no doubt that uterine disorders constitute one of the most frequent remote causes of insanity with which we are acquainted. If, therefore, the physician can ascertain that his patient has suffered or is suffering from gastric, hepatic, intestinal or uterine disease, he will have discovered a well known and frequent cause, the existence of which must be allowed to exercise its influence in the diagnosis." Mandley says: I saw melancholia of two years disappear after cure of prolapsus uteri, also another cure after relief of inversio uteri.

Griesenger reports two cures from hysterical insanity by local treatment, after failure of all other measures. These cases of inversion and prolapsus uteri I believe to produce insanity by the constant effect upon the ovaries.

Dr. Mayer of Berlin reports numerous illustrative cases.¹

Esquirol says: "Menstrual anomalies make up a sixth part of all the causes of insanity. In 6000 cases, 18.97 per cent. without and 81.03 per cent. with menstrual irregularities." Schroder Vanderkolk reports a case of melancholia from prolapsus uteri, promptly cured by replacement. Boyer relates a case of a woman insane during her first pregnancy. Ten years later, her mental alienation having returned it was thought she was again pregnant. Examination revealed uterine polypus, the removal of which cured her at once. Schlager says "in 67 of 100 cases of irregular menstruation in insane women, there were present the various minor disturbances so often observed. In the remaining 33 there were undoubtedly traces of actual disease. Insane persons who were quiet and gentle during the interval, fell into maniacal raving during the menstrual flow, not infrequently of an erotic character." H. R. Storer² says of "probable causes of derangement in New York State Insane Asylum Report for 1852, in 366 cases of insanity occurring in both sexes, in 87 or nearly one-fourth the whole number, are reported to have arisen from causes directly connected with the reproductive system. Same report for 1853 shows 117 cases out of 424 cases, or more than one-fourth the whole number." Of the many gynecologists who are on record as favoring the affirmative of this question, in the front rank stands Dr. Robt. Barnes, of London, whose admirable study of the "Correlation of the Sexual Functions and Menstrual Disorders of Women," should be read by every alienist and gynecologist. His exhaustive paper deserves far more than mention in this brief paper, as arrayed in favor of giving every insane woman as much right to relief from disease of the ovaries and uterus as her sane sister has.

Dr. Thos. Savage, in his address of 1890, delivered in the Section of Obstetrics branch of the British Medical Association, speaking of "Gynecology in its relation to Insanity," gives us no uncertain sound as to his opinion. "There is one more point I should like to refer to, and that is the necessity or otherwise that exists for most and certainly all large lunatic asylums, to have a gynecologist as a member of their medical staff. Among the causes of insanity in women, heredity, intemperance and the vicissitudes of female life are said to be the most frequent, and it has long occurred to me, as I know it has to

¹ Verhandlungen der Gesellschaft für Geburtsh. 1869.
² Insanity in Women
Brit. Gyn. Jour., Nov. 1890.

others, that in regard to the latter element as a cause, much good might result, if every case in which there was the least doubt were thoroughly overhauled and investigated by an experienced gynecologist. Every one knows that occasionally, although rarely, a case of insanity has been cured by the application of a properly adjusted pessary to a displaced uterus. Then in regard to the influence upon the mental state which is produced by the presence or absence of the ovaries, little is known. Observation on this point has not been sufficiently extended or pursued. In 500 double oophorectomies four cases of insanity; three cured; one suicide. I have never seen insanity follow removal of one ovary or any other pelvic operation. The insanity of the climacteric period, and of the puerperal period, may or may not be dependent upon some occult influence seated in the ovaries, the exact nature of which, if or where it exists, has yet to be investigated." Dr. Goodell's work in rescuing women from insanity is well known. He asserts that oophorectomy may be relied upon generally to cure insanity limited to the menstrual period, and urges early operation in ovarian insanity.⁴

Dr. Betty has cured numerous cases of insanity by his operation. Dr. Reed, our honored chairman, has reported six cases of insanity cured by such operations as oophorectomy, ovariectomy and uterine dilation. Dr. Mantou⁵ reports a case of ovarian tumor with insanity greatly relieved by operation. Dr. C. N. Hay, of New Jersey (an alienist), reports a case of insanity cured by removal of an ovarian abscess.⁶ Dr. Kitto, of Racine, Wis., a case of long standing (13 years) insanity cured by salpingo oophorectomy. The patient had pyosalpinx. Time too recent for definite result. Dr. J. B. Cummins, of Arkansas, another case with suicidal and homicidal tendency cured in seven months by oophorectomy. Immediate relief; ovaries were enlarged; adherent; subinvolution of uterus.⁷ Dr. Cottrell reports a case of menstrual insanity, melancholia, of 18 years standing, cured by removal of small but painful ovaries.⁸

Dr. O. G. Pfaff reports a case of insanity cured by removal of double pyosalpinx. Patient returned to her home in a month and continued to improve until cured.⁹

The writer has cognizance of three operations done indirectly for the mental condition. One ovariectomy a cure, one oophorectomy a cure, and one in which oophorectomy was followed by suicide in about six months, owing to persistent insomnia. Many additional cases may be mentioned, but these should suffice to prove that gyn-

ecologists do frequently encounter and relieve this dread disease among women. We claim that very many more pelvic causes of insanity exist than are found, owing to the difficulty of making a diagnosis in these cases. No fact is better understood than that any disease of the abdominal organs may favor insanity even by interference with nutrition alone. How much more does it seem probable that disease of the organs peculiar to women, which so much more than the corresponding organs in men, have to do with her physical and mental condition, may cause psychical derangement. It is unfortunate that in the past some misdirected efforts to secure gynecological supervision and treatment in asylums caused a general indisposition on the part of alienists to accord the gynecologist a place in cooperation with them. There was said to have been too keen a desire to try oophorectomy as a panacea for all kinds of insanity in women. There was also an effort made to introduce female physicians upon this tide of so-called necessity, and thus were blended disadvantageously questions of public policy, or expediency, with what should have been scientific inquiry. Dr. Spitzka's contemptuous allusion to gynecologists shows the animus of his disbelief in any cause for insanity outside the cranium. Although he readily (elsewhere) admits that insanity is intensified by pelvic disorders. He refers to one case of ill-advised oophorectomy by way of enforcing his criticism, and in general denies the claims urged by the gynecologist. Dr. Reed has pointedly suggested some improvement in asylum management. Especial reference is made to inadequacy of the medical staff in view of amount of work required. To this I add my endorsement, and respectfully suggest that the number of physicians is generally much less in asylums than in regular hospitals. The reverse should be the rule. There is also much difficulty in ascertaining how much care is taken when patients are admitted, to examine the pelvic organs for disease. I learn that in some asylums this is carefully done, as for instance in Harrisburg and Norristown, Pa., hospitals. Is it asking too much that in any doubtful case a specialist be called to assist in the investigation? Some asylum reports show excellent work done in the pathological department.¹⁰

But we do feel some regret that a full and complete history of the post-mortem appearances of all the organs of the body is not forthcoming from the pathological department of our various asylums, in order that comparisons may be made with a view to distinguish the effect of insanity upon the various organs, as well as to observe

¹⁰ This is especially true of one asylum, St. Elizabeth Washington D. C., although inquiry was made with special reference to epileptic and demented cases.

the possible relation of their disease to the mental condition. This paper would not be complete without a remark about the propriety of urging examinations and especially surgical procedures upon the insane. Sir Spencer Wells was once consulted as to legality of operating upon a lunatic, and he referred the question to Sir William Harcourt, the Home Secretary, who replied, "If she is incapable of judging for herself treat her as an infant." In the case in question the operation was done and the patient recovered her reason, and she was afterwards married.

The following circular letter was sent to twenty of our representative asylums, generally addressed to the superintendent or physician in charge.

Dear Doctor: Will you kindly answer the following questions, to be embodied in a paper which I am preparing for the approaching meeting of the American Medical Association.

1st. Have you a gynecologist on your staff of physicians or connected with your institution?

2d. Do you have any apparent need for such treatment, and do you find any cases of insanity due to disease of the pelvic organs of women?

An immediate answer will be highly appreciated.

Boston Lunatic Hospital.—"We have no gynecologist."

Very little need for gynecological treatment. Very few cases of insanity due to disease of pelvic disease in women."

Worcester Lunatic Hospital.—"In an experience of nearly twenty years I have failed to see any case of insanity due to disease of pelvic organs of women. The female member of the staff (appointed under the law of Mass.), does not find any notable amount of gynecological work to do."

The female attendant writes thus: "As I have held the position of gynecologist in this institution for some years, the superintendent has asked me to reply to your questions, which I am pleased to do, as follows: There is a resident gynecologist on the staff of the hospital. There is undoubtedly need for such treatment, and while I am not convinced that uterine disease is often the sole cause of insanity, yet I think it is frequently one of the factors, the remedying of which assists greatly in the recovery of the patient."

Danvers Lunatic Hospital.—"Your letter received. . . . I wish to add that the practice in Massachusetts of having a woman doctor in each insane hospital meets my hearty approval."

The gynecologist of this institution at the request of the superintendent, writes thus: "Although examination is made of all new cases, few occasions for surgical work."

There are often cases which could be relieved of discomfort by operative treatment, but it is not attempted, owing to expense and subsequent cure, which would be difficult in pauper class,

It is not evident that many cases of mental disturbance are due to uterine lesions. That the functional activity of the uterine system has a close inter-relation with psycho-pathological states is patent to the least experienced psychiatrist. That a wise, legitimate activity, in gynecology, (not a wholesale use of invalids to swell the records of the tyros) is called for, the constant questioning of the last decade from every quarter renders apparent. There also seems needed full sustained authority, and complete provision, in order to overcome the well-known difficulties due to the mental status of the patients. This implies expense and attention, which the hospitals of to-day are not prepared to give."

Westborough Insane Hospital, Mass.—"We have a female physician on staff as required by law of Massachusetts. She has every day some cases under treatment, out of nearly three hundred women. There are always some that are benefited by her care. Treatment is useful and comforting, rather than curative. Cases of insanity due to pelvic disease rare."

Taunton Lunatic Hospital.—"Have a gynecologist, sometimes find cases of insanity in women due to disease of the pelvic organs but they are quite infrequent."

McLean Asylum, Mass.—"One member of staff has had gynecological training. No greater need for gynecological work in insane than in same number of sane women. A specialist in this department called when required."

Warren, Penn., State Hospital for the Insane.—"No gynecologist; not cases enough to justify such an appointment. Agrees with Dr. Goodell that the large majority of uterine troubles are nervous, requiring little or no operative interference. Very few cases of insanity arise from uterine troubles simply."

Pennsylvania Hospital for Insane, Harrisburg.—"We have two female physicians who do considerable gynecological work."

The physician in charge of female department writes thus: "I think there are some cases of insanity which are apparently referable to pelvic disease, and many more complicated and intensified by such troubles. Many of our patients are drawn from a class of people who from ignorance or neglect, have often not had proper attention during or after confinement, and suffer from the ills consequent upon neglect, privation, or overwork. Some of our puerperal cases furnish the best illustration of the need of gynecological treatment and the benefit resulting from it. We always have a large number of patients here under treatment and find that they are always more or less improved by relief from suffering of that

NOTE: I do not believe Dr. Goodell is generally thus misinformed. Would it not be better to say so-called "uterine troubles"? The "gynecologists of uterine diseases" are generally well understood by gynecologists who perhaps all agree with Dr. Goodell, who has written so much on this interesting and important subject.

sort. From my experience I am decidedly of the opinion that there is room, yes, necessity for the work of the gynecologist among insane women. . . . We know the frequency of pelvic disorders among more fortunate people, and it follows that among this class such diseases will be found in greater proportion than in the general population."

Pennsylvania Hospital for Insane, Philadelphia:—"We have a female consulting gynecologist. Non-resident. Examinations for suspected pregnancy or pelvic disease. Insanity due to disease of pelvic organs extremely rare. I will not say they never occur, as some are of the opinion they do occur. Examinations have a negative value."

Philadelphia Hospital for Insane:—Blockley. "No gynecologist on staff. Cases now and then admitted who need treatment of their pelvic organs, but such cases are rare. Have seen no cases of insanity due to disease of pelvic organs."

Friends Asylum, Frankford, Pa.:—"Have a non-resident gynecologist. No more need of gynecological treatment than in any hospital where same number of women are congregated. Never saw a case of insanity in which I could say it was entirely due to diseased condition of the pelvic organs. Such disease of pelvic organs often complicated with nervous disorders which have ultimate relation with mental condition and may be improved by treatment."

State Hospital, Norristown, Pa.:—Physician in charge of female department says: "I do not know of any hospital where there is a gynecologist proper. Do not see why the regular attendants should not do such work. My impression is that but little is done. Hospitals as a rule overcrowded; often the number of physicians too small, and so far as I know anything about it, physical examinations even in some reputable hospitals are not made at all. The questions implied in the title of your paper must be answered affirmatively, irrespective of what has or has not been done. It is a question of what ought to be done, and I think we shall never know much about insanity until underlying bodily conditions are more carefully studied. Here every patient is examined upon admission; not many cases due entirely to disease of generative organs. An occasional case is positively benefited by such treatment. In a very large number of cases the local trouble is one of many depressing causes and we believe that appropriate treatment aids often."

Pennsylvania Hospital for the Insane, Danville:—"We have no gynecologist. There is same need for a gynecologist as for an oculist, or surgeon, and no more. Cases do occur where a gynecologist on staff would be of service. Cases occur showing marked sexual derangement as far as their history and conduct indicate, nothing found on examination, and they recover

under other than gynecological treatment. I believe gynecological treatment would be of disadvantage in some cases. Disease of pelvic organs, as of any other organs of body, such as heart, etc., may be a factor in the causation of insanity, but uterine disease is not likely more frequently a cause than disease of other organs."

Utica, New York, State Hospital:—"There is no gynecologist on the staff. Thus far no need for one. Very few cases of insanity directly traceable to disease of pelvic organs of women."

Binghamton, New York State, Hospital:—"We have a female physician who looks after gynecological cases. We doubt not that in certain cases treatment of this character is desirable, and beneficial. Of course there are cases of insanity more or less intimately connected with diseases of pelvic organs in women."

Anna, Ill., State Hospital for Insane:—"We have no gynecologist on our staff. The physician in charge of female department attends all diseases pertaining to the female organs, that come into the hospital, and there are a good many in the course of the year. There are a few cases where insanity appears to be brought about through reflex influence of the nervous system, as there are no other marked or well founded causes known, and under treatment for this morbid condition of the genital organs, many improve."

Illinois Eastern Hospital for the Insane:—"We have female gynecologist. There are many patients who need and are benefited by such treatment. I have not seen any cases however, in which I attributed the insanity exclusively to disease of the pelvic organs."

Illinois Central Hospital:—"We have no special gynecologist; nevertheless much gynecological work is done."

We think there is great need of gynecological treatment and for the same reasons that it would be needed outside of a hospital for the insane. I presume pelvic disease does to some extent, exert an influence upon the mind through the nervous system."

The answers above quoted are as briefly given as possible, and although received after the body of the paper was written, show that some of the conclusions were correctly drawn. It will be plainly observed that the majority do not agree that insanity is often caused by pelvic disease. On the other hand very many admit that gynecological treatment is important as assisting in the cure. One very marked and positive conclusion is drawn from this paper, that the gynecologist can aid the alienist, as shown by the very positive statements of those who have the actual work of caring for those unfortunates. In conclusion, I must again call attention to Dr. Barnes' valuable paper and also give him credit for much information embodied in this article.

PAPILLOMATOUS CYSTOMA OF THE OVARY, WITH REPORT OF A CASE.

Read by the Section of Obstetrics and Diseases of Women, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY A. B. WALKER, M.D.,
OF CANTON, O.

Papillary cysts of the ovary are quite rare compared to other varieties of ovarian cysts. They are composed of small cysts, multilocular in form. The smaller cysts are usually irregular in size, and have villous growths and papillary vegetations attached to the inner surface of the cyst wall. Papilliform growths are frequently found on the outer surface of the cyst. The fluid contents of these cysts vary in color from a light straw to a dark wine color. These cysts may be mixed, the glandular and papillary types combined.

These papillary cystoma of the ovary, as a rule, are claimed to take their origin from the traces left of the Wolffian tubules in the hilum of the ovary, and, as with all other growths, grow in the direction where there is the least resistance, which in this case would be between the folds of the broad ligament instead of in the stroma of the ovary. They may grow to be quite large, filling the pelvic cavity, and if unilateral, the uterus will be pushed to one side, while if bilateral, the uterus will be completely hidden from view; or they may push their way up into the abdominal cavity, either single or double, at the expense of the anterior or posterior portion of the broad ligament, and still be extra-peritoneal, growing in front, behind or between the folds of the peritoneum. They may, very early in their growth, break through into the peritoneal cavity and become intraperitoneal, growing then among the intestines and other abdominal organs, or they may take their origin primarily from the intraperitoneal surface of the ovary and start as any other ovarian cystic tumor, either direct from a Graafian follicle, or from a dropsical follicle; but why these cysts should take on the papillary form is as yet unknown to pathologists. It was formerly thought that papillomata were only to be found where papillae were found, as the skin, mucous membrane and the like; but that view was soon changed, and we now find that papilloma may develop from any epithelial surface. It is rare, however, to find them taking their origin from a serous surface. As condylomata and villous growths, tumors of the variety of papilloma, are caused by erosive fluids or irritant matter when they are found on the genital organs, why not attribute the origin of papillary cystoma of the intraperitoneal surface of the ovary to the same cause, which in this case the irritant matter may escape from the fimbriated extremities of the Fallopian tube during gonorrhoeal infections, pyosal-

pinx or tubercular pus, or of other irritating materials that may gain admission in this way.

These papillomatous cysts are very liable to rupture; in fact, a papillomatous growth within the cyst greatly increases its liability to rupture, but as the fluid is benign, there is no danger from its presence either in or on the peritoneum, but after the rupture of one or more of the cysts, the growths are very likely to become attached to any organ or organs they may come in contact with. This is true in particular of the cauliflower form. These ovarian papillomatous tumors are, as a rule, benign, and are not likely to return after their removal. The only trouble to fear is from their extensive attachments to the abdominal organs, which may be so great as to preclude their removal, for they are quite brittle and vascular. In cases reported where all of the growths could not be removed, the portion left was seemingly absorbed. It caused no further trouble, at least, and the patients recovered. These tumors, like other cystic tumors of the ovary, should be promptly removed.

The following case came up in my practice: Mrs. M. R. H., a bright and intelligent woman, aged 44 years, married, wife of a farmer, mother of three children, family history good, enjoyed fair health until birth of first child twenty-four years ago, after which time she complained of distress and pain through uterus and ovaries. After having an attack of typhoid fever eight years since, suffered from pain across lower part of bowels and through her back. About this time she noticed uterus to be retroflected and, as her condition continued to grow worse, she consulted a physician two years later, who, after examination, claimed that her cervix was lacerated and was the cause of all the trouble, and recommended an operation. Six months later another physician was consulted, and claimed all her trouble came from endo-cervicitis, and gave several treatments for same, without any improvement whatever. Three years ago a third physician diagnosed a small tumor in left side, and recommended an operation, but there being such a difference of opinion, the fourth physician was consulted, who claimed that she had a fibroid tumor, and advised that it be let alone. He being an aged man, a physician of much experience, his advice was taken until last November, when she became so miserable and increased in size that she finally, through the advice of friends, went to a hospital in Ann Arbor, Mich., where she remained five weeks for treatment, which consisted of two examinations before a class of students and very free purgation, with no relief. The opinion of the physicians there was, that she had a malignant tumor or growth connected with the liver, probably cancerous, and that her case was not one for an operation.

About January, 1890, she noticed herself becoming larger, and that she was losing in flesh.

The 1st of February, 1891, I was called to visit her, when I found her very thin and emaciated, with a very large abdomen. The enlargement was marked and resembled ascites. She was suffering with proclitica. The whole of her uterus and posterior cul-de-sac protruding, the mass together being as large as a fetal head. She stated that this mass had been out and enlarging since before her visit to the hospital, and that no attempt had been made to replace it. The free purgation she was subjected to there made it much worse. Two abrasions the size of a silver half-dollar were on the posterior part of this mass. She was simply eking out a miserable existence, growing larger daily at the expense of her flesh and strength. I replaced the mass in about two minutes by placing her in the genito-pectoral position, and had it retained in place with a large cotton ball covered with vaseline in vagina, and a T bandage. But little time was spent in making a further examination, as I had learned from past experience that a positive diagnosis could not be made, in particular where the abdomen contained so much fluid. Felt satisfied, however, that the trouble originated with the uterine organs, and that it was in no way connected with the liver. After an examination of her heart, lungs, urine, etc., decided to make an exploratory incision, and remove, if possible, the cause of her trouble. After a thorough preparation of the patient, I opened her abdomen on the 12th of February last, assisted by Dr. E. O. Morrow, of Canton, O., and Dr. G. E. Hambleton, of Louisville, O. The abdominal wall was very thin, a marked absence of adipose tissue. When the peritoneum was opened about three gallons of ascitic fluid were removed, which was of straw color, which then enabled us to get at the real cause, which proved to be a large papillomatous tumor of the left ovary, attached to the ovary, Fallopian tube and broad ligament. With but little difficulty we succeeded in grasping the Fallopian tube and broad ligament close to the cornua of the uterus with a large ovarian forcep, where, with a knife, the growth, weighing 3½ lbs., was removed. The pedicle being quite broad, was first transfixed, then tied with a No. 12 braided, iron-dyed, silk ligature. The abdomen was then thoroughly cleansed with warm distilled water, and closed with No. 8 iron-dyed sutures. The operation was aseptic in every particular, and lasted three-quarters of an hour. The patient rallied well, and seemed to experience but little shock. Ether was administered, its administration preceded by a hypodermic injection of morphia $\frac{1}{4}$ gr., and atropia $\frac{1}{100}$ gr., and an ounce of brandy internally. Next day after operation, 13th of February, 10 A.M., pulse 124, temperature 100.2°. The 14th of February, 10 A.M., pulse 130, temperature 99°, very weak, vomited for the first time, stomach would not tolerate any

food or milk, when we were necessitated to give rectal injections of beef juice, eggs, peptonized milk and brandy to sustain life.

February 15, patient much better and stronger, pulse 100, temperature 99.4, some disturbance of bowels during the evening, which was promptly removed with enema of hot water and the passage of a long rectal tube.

February 16, pulse 92, temperature 100.2°, strength returning. A discharge of blood from uterus noticed, which continued thirteen hours.

February 18, 10 A.M., pulse 84, temperature 99.5°, still gaining in strength.

February 19, 10 A.M., pulse 88, temperature 100. Wound dressed for the first time, which looked well. Union by first intention. Every other suture was removed. The 20th, no report.

February 21, 10 A.M., pulse 80, temperature 99.4°.

February 22, 10 A.M., removed the remaining sutures. Pulse 84, temperature 99.4°.

February 23, 10 A.M., pulse 84, temperature 98.6°.

February 24, 10 A.M., pulse 80, temperature 99.2°.

February 25, 10 A.M., pulse 84, temperature 99°.

She made a good recovery. Sat up for the first time on the twenty-first day, and weighed 84 lbs. Her menses have appeared regularly since. Her uterus remains in, but is drawn over to the left side. She now weighs 105 lbs., and feels better than since birth of her first child.

A microscopical examination of this tumor, made by Dr. C. H. Evans, of our city, showed that the entire tumor was composed of small papillae and multiple cysts.

45 West Tuscarawas St.

PREVENTION OF PUERPERAL ECLAMPSIA BY THE INDUCTION OF PRE-MATURE LABOR.

Read in the Section of Obstetrics and Diseases of Women at the Forty-third Annual Meeting of the American Medical Association, held at Washington, D. C., May 1901.

BY HENRY D. FRY, M.D.,

OF WASHINGTON, D. C.

In February, 1883, I presented a paper to the Washington Obstetrical and Gynecological Society on the etiology and prophylactic treatment of puerperal eclampsia, and I desire, with your permission, to quote the conclusions arrived at by a study of the subject offered at that time.

They were:

1. Albuminuria, occurring during pregnancy, is the sign of a pathological change, or of pathological changes, indicative of a predisposition to eclampsia.

2. The prophylactic treatment of eclampsia,

therefore, includes measures adopted to prevent the occurrence of albuminuria. These are, to improve the condition of the blood by the administration of tonics, iron, and a liberal dietary; and to relieve the renal congestion by attention to the functions of the skin and by prohibiting the wearing of tight clothing.

3. The urine of all pregnant women should be systematically examined for albumen after the fifth month of utero-gestation, and earlier if any suspicion be entertained of renal complication.

4. With the recognition of the affection treatment should be directed to its relief. This is divided into general, dietetic, medicinal, and

5. Obstetrical. The latter comprises the graver cases of the disease which not yielding to treatment, demand, by the urgency of their symptoms, prompt operative interference. During the years that have elapsed since that paper was written, I have carried out the conclusions above presented, and have not had a single case of puerperal eclampsia to occur in my own clientèle. Albumen was found in the urine of a certain proportion of the cases, but by treatment it either disappeared or remained small in amount and gave rise to little apprehensions, except in a few instances. These few instances form the subject of my present observations and bring up the question of operative interference in the class of cases referred to obstetrical treatment. The amount of albumen in the urine does not alone furnish evidence of the gravity of the case. Convulsions have been noted when no albumen existed in the urine, and yet post-mortem examination revealed serious organic disease of the kidney. The total quantity of urine passed in twenty-four hours, the amount of solid ingredients contained, together with the symptoms of the patient, furnish criteria for action. Serious toxæmic symptoms may manifest themselves when only a trace of albumen in the urine had produced a feeling of security.

Examinations of the urine should be made every few weeks and oftener if there be any indication of renal insufficiency. The specimen examined should be taken from the entire quantity passed in twenty-four hours, this amount must be ascertained, and the specific gravity estimated. These results furnish evidence whether further investigation (microscopic, etc.), is called for.

When serious symptoms develop and treatment has proved unavailing, the induction of premature labor offers the hope of saving mother and child. Fortunately the question of ending gestation is rarely brought up for consideration, before the seventh month. The child is then viable and has a better chance of surviving if born prematurely than if allowed to remain and be nourished by the poisoned blood of the mother.

The nearer gestation has approached its normal

duration before labor begins, the better, but if the symptoms are threatening it is unwise to delay on this account. Better act a little too soon than too late.

The use of the *couvuse* increases materially the chances of survival of the premature or feeble infant. Out of 829 premature children whose average weight was four and a half pounds, 662 lived, and recently infants have been saved by use of the *couvuse* when only six months advanced in intra-uterine life. By the employment of artificial feeding or gavage in combination with the *couvuse*, the viability of the infant may be placed at six months.

By these means Tarnier¹ has succeeded in saving children at 6 months, 30 per cent.; children at 7 months, 63.6 per cent.; children at 8 months, 85.7 per cent.

The following case recently came under my observation and represents the advantages of this line of treatment.

Mrs. X., æt. 30, a primipara, was placed under my care by Dr. N. S. Lincoln, on November 4, 1890. She had arrived in Washington a few days before after a very trying journey across the continent. Until she reached Chicago she had entire charge of an invalid mother, and being compelled to wait on her at night she contracted a cold. When I saw her she complained of shortness of breath, loss of voice and sore throat. She also suffered from insomnia, headache, nausea, and at times vomiting. She was anarsarcous. Pregnancy had advanced to the seventh month. Fœtal movements were distinct, the heart sounds normal and situated below and to left of the umbilicus.

On the next day, November 5, a specimen of urine was obtained and on examination was found to contain 21 per cent. of albumen. The microscope revealed the presence of hyaline casts in large quantities. The patient was kept in bed, a hot bath, temperature of 100° given daily and flannel worn day and night. The bowels were moved daily by sulphate of magnesia. Diet consisted of skimmed milk.

November 6, 24 $\frac{3}{4}$ urine passed, sp. gr., 1010, albumen 21 per cent.

November 7, 16 $\frac{3}{4}$ urine passed, sp. gr., 1018, albumen 19 per cent.

November 8, 14 $\frac{3}{4}$ urine passed, sp. gr., 1016, albumen 21 per cent.

November 9, 17 $\frac{3}{4}$ urine passed, sp. gr., 1026, albumen 31 per cent.

November 10, 22 $\frac{3}{4}$ urine passed, sp. gr., 1018, albumen 24 per cent.

November 11, 24 $\frac{3}{4}$ urine passed, sp. gr., 1023, albumen 27 per cent.

November 12, 14 $\frac{3}{4}$ urine passed, sp. gr., 1017, albumen 18 per cent.

November 13, 12 $\frac{3}{4}$ urine passed, sp. gr., 1023, albumen 27 per cent.

As the condition of the patient did not im-

¹ Budin: quoted in Amer. Sys. of Obstet., Vol. II, p. 201.

prove under treatment, and the amount of urine excreted each 24 hours remained so much below normal, I feared to delay longer. The short breathing, which was particularly distressing at night, I attributed to uræmic poisoning of the nerve centres. The lungs were perfectly clear. The insomnia, nausea and headache were unrelieved. My suggestion to induce labor met with Dr. Lincoln's approval, and after conferring with the husband of the patient, and at his request, Dr. J. Taber Johnson's counsel was sought.

Dr. Johnson saw the patient with me on November 13, and considered favorably the propriety of inducing labor.

Preparations having been made already, the patient was placed in position and the parts exposed with a Simm's speculum. After cleaning the vagina and cervix with a carbolized solution, a bougie was passed full length between the membranes and uterine walls.

Pains set in after six or seven hours and continued with varying intensity during Thursday night. The head presented in first position and beyond a slight descent into the pelvic cavity, little change took place during Friday. The cervix retained its full length and was dilated sufficiently to pass the finger to the internal os. Early Friday night the membranes ruptured spontaneously; later, the internal os dilated and the cervical canal became obliterated. The external os dilated irregularly; the half on the right side remained thick and undilated. The left half became thin and retracted. The opening, in consequence, was situated on one side, and the thickened right edge occupied the middle of the vaginal passage. At 8 o'clock Saturday morning the os was about two inches in diameter, and as I feared to temporize longer, I requested that Dr. Johnson should see the patient again.

He arrived promptly, and after making an examination, considered it advisable to apply the forceps and employ it for the purpose of dilating the os. The patient was put under the influence of chloroform and the right blade inserted before the left. The blades were applied in this manner because the adjustment of the right blade brought the displaced os into the centre of the vaginal passage and facilitated the application of the second branch.

Intermittent traction was made until the os had dilated and delivery was then effected without further trouble. The perineum was uninjured, but there was a slight tear, about one inch in extent, of the vaginal mucous membrane on the right side of the median line posteriorly. This was closed with a continuous silk suture.

The infant, a female, measured eighteen inches in length and weighed five pounds and a half. It was asphyxiated at birth, but soon responded to peripheral irritation and cried lustily.

The mother had a normal convalescence and on the second day after childbirth, the amount of albumen in the urine had decreased to 8 per cent. The total quantity passed each twenty-four hours varied from 50 to 70 ounces. Examination of the urine made recently failed to detect any albumen or casts, and the mother has fully recovered her health.

The infant was placed in the *coucouse* and the temperature maintained at 100° F. for ten days, and then at 90° for three weeks longer. At the end of the fourth week it was sufficiently developed to be removed from the apparatus.

The mother being unable to nurse the baby, the food consisted of diluted peptonized milk with the addition of cream. Later, the proportion of cream was increased and milk sugar added. At first half an ounce was administered at a time and subsequently the amount increased in proportion to its needs. Sterilized milk was finally substituted for the above and gave better results.

At the end of the first week the baby had lost half a pound; at the second its weight was the same; at the third it had gained half a pound, and from this time it increased in weight at the rate of one-half to three-eighths of a pound weekly.

To further emphasize the value of this method of treatment, I wish briefly to mention the following additional cases that came under my observation.

On June 17, 1888, I induced labor at the thirty-fourth week under the following circumstances.

Mrs. F., at her third pregnancy, had considerable albumen in her urine and some evidence of toxæmia. I felt no little apprehension when her labor came on, but she passed safely through the ordeal. Her convalescence was extremely protracted owing to co-existent cardiac disease.

The fourth pregnancy and labor were very similar to the preceding, and convalescence likewise protracted.

In the fifth pregnancy the conditions were very much aggravated in spite of energetic treatment. Violent headache and impaired vision were prominent symptoms. At eight months and a half, as stated above, labor was induced by the introduction of a bougie. The uterus responded after a few hours delay and the child was born without the appearance of any alarming symptoms in the mother. Convalescence was rapid and she sat up on the tenth day. In this case organic disease of the kidneys was compatible with fairly good health, except when pregnancy existed. Each succeeding pregnancy presented graver symptoms.

Of the three children born in these labors, the only one living at present is the one prematurely born by induced labor. Both the others died

from intestinal diseases when a few months of age. The next two cases were seen with Dr. W. W. Johnston, and occurred within two weeks of each other.

Mrs. M., a primipara, advanced about eighth month, presented serious symptoms despite treatment directed for relief of albuminuria. Nov. 27, 1888, labor was induced by the introduction of a bougie into the uterine cavity. Unusual difficulty was met with in performing this little operation on account of the existence of what has been so fully described by Dr. Busey, as cystokolpocele. The red tumor formed by the projection of the vesico-vaginal wall so completely blocked the genital passage, that it baffled all efforts to insert the instrument. One variety of speculum after another was tried and abandoned. Finally, by touch the bougie was placed in position. Labor pains came on in due time, and when the os had dilated the child was delivered by forceps applied to the breech.

Mother and child recovered.

The last case, also a Mrs. M., a primipara, presented alarming symptoms during the latter part of her pregnancy. On December 10, 1888, the bougie was placed in position. The uterus failing to respond to the irritation, it was removed and a second one inserted in a different direction. Feeble uterine action was supplemented by dilatation with Barnes' bags, the smallest size being replaced after a few hours by the largest. When the os had dilated, labor was terminated with the forceps. Several hours afterwards the mother had convulsions and for a time was in a critical condition. She finally recovered and the child lived.

These four cases offered every reason to fear an outbreak of eclampsia, and only after energetic treatment had been directed, without success, to the relief of the renal complication, was premature labor induced. This result emphasizes the value of the induction of premature labor for the prevention of eclampsia. While the consensus of opinion may be said to favor such action, it is nevertheless true that some eminent authors fail to endorse operative interference.

The safest, simplest, and consequently, at present, the best method of exciting uterine contraction is the insertion of a bougie between the membranes and the uterine wall. The term catheterization, which is often employed to signify this method, should be discontinued, as the catheter is an unsuitable instrument to use for the purpose. Being hollow, with a hole at both ends, it is easily soiled and with difficulty cleaned. Even if aseptic when used, secretions accumulate within the tube and readily undergo decomposition. The bougie should be prepared by soaking for twenty-four hours in bichloride of mercury solution 1 to 1,000, and then washing in boiled water just before use.

I prefer to insert it by exposing the parts with Sim's speculum and steadying the cervix with the aid of a tenaculum. The end of the bougie is bent at an obtuse angle and guided around the curve of the lower uterine segment. A boricated cotton tampon is placed in the vagina to prevent slipping of the bougie, and to absorb the discharges.

If this treatment fails to excite uterine action the instrument can be removed and a fresh one inserted in a different direction. The majority of cases will meet with success, but occasionally the organ is provoked to contract with great difficulty. Other means, familiar to all, can be resorted to for the purpose of exciting action.

A method recently suggested by Schrader is worthy of trial. It is the alternate application of hot and ice cold fomentations to the abdomen, changes being made every five minutes. Lomer has reported a case in which he succeeded in inducing labor by this means for impaired vision resulting from albuminuria. Pain developed in two hours and in six the child was born.

Full doses of quinine and hot vaginal douches are useful to strengthen uterine pains after they have been started by other means.

Agents to soothe the nervous system and deaden sensibility are valuable during labor to diminish the liability to convulsions. The best of these are morphia hypodermatically, chloral by the rectum, and the inhalation of chloroform. Morphia should not be employed too early as it might arrest uterine action. Chloroform given only to the obstetrical degree meets the indication and aids the dilatation of the os. When dilatation progresses slowly, the early application of forceps, as advocated by the late Isaac Taylor is a justifiable procedure. If labor pains are strong and no delay arises the completion of labor should be left to nature.

If, in any case, operative interference be demanded, chloroform should be the anæsthetic employed. Ether will increase the renal congestion and might precipitate what we have used all our efforts to avoid.

In conclusion it may be well to suggest one other precaution to be taken in these cases. The impaired function of the kidneys increases greatly the dangers of using corrosive sublimate and carbolic acid solutions for vaginal or intra-uterine irrigation.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.—The meetings of the Congress of American Physicians and Surgeons will be held in Washington, from 3 to 6 P.M., September 22, 23, 24, and 25, 1891.

THE OPERATIVE TREATMENT OF EXTRA-UTERINE PREGNANCY AT OR NEAR TERM, WITH REPORT OF A CASE.

Read before the Illinois State Medical Society, May 11, 1891.

BY CHRISTIAN FENGER, M.D.,
OF CHICAGO, ILL.

It is not my intention in this paper to give an exhaustive exposé of all the details and the questions that arise in late extra uterine pregnancy, but merely in connection with a case of this kind, which terminated fatally, to describe the thoughts and reflections that presented themselves to me in connection with the case.

I shall, then, first describe the case, the different methods of operation and their prognoses, and later, review the more important points in the management of such cases from my own experience and from the literature as far as I have been able to obtain it.

Case.—Mrs. C., 34 years of age, married thirteen years. Healthy as a child; first menstruated at the age of 14; always regular; three days' duration; for the past ten years two days only; never very abundant. A slight leucorrhœa for a few days following menstruation. Married at 21; a year later, after a normal pregnancy, was delivered of a female child who lived only ten days. Labor was difficult, but forceps were not used. Slight laceration of perineum. She was in labor from midnight until half-past ten the next morning. She had puerperal fever and pelvic cellulitis which confined her to bed for three months. She had a slow convalescence, not being well until three months later. Menstruation returned five months after the birth of the child, and since that time, about ten years ago, has been always regular. She has occasionally had slight leucorrhœa, but otherwise has had no symptoms of disease of the genital organs excepting sterility.

March 20, 1890, she had her last normal menstruation. Two or three weeks later, in April, she felt sick, wanted to eat, but after eating would often feel nauseated. May 15, at noon she suddenly felt a severe pain through the anterior part of the abdomen and the rectum, followed by vomiting. These symptoms lasted for ten days, during which time she was obliged to stay in bed. No fever, no symptoms of hæmorrhage. The symptoms then disappeared and after three weeks she resumed her work of teaching school. She was well until July when a sudden attack of pain which came on at night while she was in bed, necessitated her keeping quiet for a few days. After this time pain would often come on during the night, extending from the abdomen down to the knee, more severe in the right leg. August 5, she had a sudden, severe attack of pain and vomiting which kept her in

bed for two weeks and necessitated her stay at home for two weeks longer. During this time her temperature was normal.

Between the fifth and tenth of August, while in bed with this apparent attack of peritonitis, she first felt fetal movements, faint at first, later stronger. These continued to be felt until December 29. Uterine hæmorrhage with passage of a decidual membrane was never observed. During September, October and November, she was able to be up and about attending to her work in school, but almost every evening she would have pain in the abdomen, which would be aggravated on change of position, and would prevent her from sleeping in the early part of the night. In the second week of December the abdominal pain increased and also came on during the day, so that for fear the pain would come on, she did not dare go out of the house.

December 31, spurious labor set in with severe pain in the left side of the abdomen increasing toward night, which lasted for two days. At this time fetal movements ceased. She remained in bed three weeks, during which time the abdomen commenced to decrease in size. February 10, 1891, six weeks after the death of the child, there was a sudden recurrence of the abdominal pain with vomiting and rise of pulse and temperature.

February 11, I made an examination. The patient was in bed, somewhat pale, pulse 100, temperature 100.² She had been suffering from pain and vomiting for two days, but at this time the vomiting had ceased. The mammary glands were large, areolæ, pigmented and abundance of milk coming from the nipples on pressure. The abdomen was enlarged to about the size of pregnancy at term, but more prominent on the left side, with an area of dull percussion up to the body of the ninth rib, while on the right side it did not extend to within two inches of the lower border of the ribs. Tympanitic percussion in the epigastric and both lumbar regions; dull percussion over the umbilical, hypogastric and inguinal regions.

Through the abdominal wall could be felt a harder, round portion of the tumor to the right of and above the umbilicus—the fetal head. Over the remainder of the tumor no distinct fetal parts could be felt. In the territory below a line extending from the border of the right ribs downward and inward, to midway between the umbilicus and symphysis pubis, and from here to the outer third of the left Poupart's ligament, a distinct placental souffle could be heard, most pronounced in the right hypogastrium.

On vaginal examination, the vaginal portion of the uterus was shown to be somewhat flaccid, standing high up and directed forward against the symphysis pubis. The posterior lacuna was pushed downward into the vagina by a doughy,

immovable tumor, probably the placenta, as no fetal parts could be felt. The patient complained of frequent micturation, that she was obliged to pass water every hour except when asleep. The urine was normal in quantity and color and contained neither pus, sugar nor albumin.

I resolved to wait for the cessation of the placental circulation, as might be indicated by the placental souffle, keeping the patient in bed and under symptomatic treatment.

February 10. Area of placental souffle diminished about one-half.

February 22. No placental souffle could be heard. The patient was removed to the Emergency Hospital for operation, which was fixed for a week after her arrival there.

February 25. Diarrhea set in with slightly bloody stools, the passages soon becoming chocolate-colored. On microscopic examination no pus cells were found, but fecal matter, fine granular matter and blood corpuscles. Pulse and temperature increasing.

February 28. Pulse 110; temperature 103°. She had several passages of a dark, reddish-brown color. Concluding from this that perforation of the sac into the bowel had taken place, and consequently that sepsis had commenced to appear in the sac, operation at once became necessary.

March 1. Operation. In the presence of the doctors from the Policlinic, Dr. Bellinger, of Council Bluffs, Iowa; assisted by Drs. Bernauer, Hall and Brohm. Chloroform given by Dr. Rosa Engert. Percussion at this time over the entire tumor was tympanitic where it had formerly been dull, showing the presence of air in the fetal sac from perforation of the intestines.

An incision was made in the linea alba, seven inches long, from a point midway between the symphysis pubis and umbilicus, to three inches above the umbilicus. The parietal peritoneum was loosely adherent to the wall of the sac downward; above was the free peritoneal cavity. The sac was here covered with omentum containing a large number of dilated vessels, some of the veins two or three lines in diameter, while most of the adipose tissue of the omentum had disappeared. The parietal peritoneum was united by sutures to the skin. As the adhesions between the parietal peritoneum and the omentum were incomplete, I separated the remaining adhesions with the hand, and packed large sponges into the peritoneal cavity all around the incision, or rather around the territory where the opening of the sac was to be made.

On account of the numerous and large vessels, double ligature of which would have taken too long, I opened the sac with a Paquelin cautery knife. This was used only at red heat. There was considerable hemorrhage from the omentum,

necessitating numerous ligatures. On opening into the sac there was an escape of fetid air, and later on a discharge of a thin, grayish, fetid fluid of fecal odor. During this time the patient was turned on the side and the wound flushed with warm sterilized water.

The incision was now prolonged six inches. The child presented with the back and left shoulder in the wound. The left arm was first drawn out, but as it was found impossible to deliver the head, the arm was replaced and the left leg drawn out, then the right leg, and thus the child was delivered. After incising the tympanitic abdomen, which collapsed after the escape of the gases, extraction was now easy without violence to the wall of the sac. The umbilical cord was tied two inches from the placenta, at the lower border of the wound. The fetal cavity contained fetid, chocolate-colored fluid and smegma. The patient was now turned on the side and warm sterilized water poured in from a pitcher to flush the cavity until it became reasonably clean, the water being mopped off with large sponges. The large placenta entirely filled the small pelvis and the right iliac fossa up over the surface of the transverse colon. The uterus could not be seen, as it was covered by placenta. The cord was attached down near the symphysis pubis, was of a whitish-gray color and macerated on the surface, showing no signs of circulation. The fetal surface of the placenta was smooth and bluish-gray, looking as if the circulation had ceased.

An attempt to cleanse the inside of the sac by means of soft sponges on long artery forceps, the borders of the sac being held apart by the hand, was immediately followed by a sudden gush of bright red arterial blood from the borders of the placenta, which necessitated immediate packing of the cavity with large pieces of gauze. The deepest part of the sac was in the left iliac fossa where, to the left of the placenta, the distinct contour of loops of large intestine, probably the descending colon and sigmoid flexure, were distinctly seen. They were felt to be covered with a layer of tissue so thin as to indicate that no sac wall existed. No perforation into the bowel could be seen at any point and no escape of gases from the bowel into the sac was noticed, but the contents of the sac had a distinctly fecal odor. A thorough search for the opening into the intestine was not made, as even the slightest manipulation caused copious hemorrhage from the borders of the placenta.

The large sponges were now removed from the peritoneal cavity, which was then cleansed by means of smaller sponges on long forceps, and the borders of the sac united to the skin by sutures. Strips of iodoform gauze, for capillary drainage, were introduced between the sutures at six different places to a depth of about two inches

between the sac and the abdominal wall. One strip at the right upper border of the wound was introduced four inches, up under the liver. A handful of a mixture of equal parts of salicylic and tannic acids was strewn over the inner wall of the sac and the whole cavity packed loosely with sterilized gauze impregnated with the same powder, of which four ounces in all was used. The wound of incision into the sac was left open and over the packing an antiseptic dressing was applied.

The child was a normally developed male at full term. Instead of commencing maceration, the epidermis was covered with smegma, and in many places was loosened from the corium, which presented a brownish-red, discolored surface.

At the end of the operation, which lasted an hour and a half, the pulse was 150, and reasonably strong; color natural. Half an hour after the operation, pulse 120. Seven P.M.: temperature 100°; pulse 120; no vomiting; the patient has some pain in the sac and the wound; skin moist, expression natural. She has slept for a short time and does not complain much.

March 2. No vomiting; has slept a little and taken some boiled milk; pulse 120; temperature 101°. The outer dressing, which contained a great amount of thin, grayish fluid of fecal odor, was changed.

March 3. A very little discharge in the dressings. Pulse 110; temperature 101°. She takes liquid nourishment and has a moderate amount of pain, which can be controlled by morphine.

March 5. Two stools of a chocolate-colored fluid containing many small clots of blood. Very little secretion from the dressings.

March 6. Three copious evacuations of a bloody fluid containing several clots as large as a hen's egg.

March 7. Last night and this morning several large coagula and liquid blood passed through the rectum. The patient is pale, extremely anemic, conjunctiva pale, exsanguinated, pulse 130, weak; temperature 99.5°. The patient is fully conscious, and complains of extreme weakness. Skin of extremities and face cold. Infundation of sixteen ounces of slightly alkaline, saccharated saline solution into the cephalic vein. In the evening pulse 120, stronger, and the extremities warm after the application of hot water bottles.

March 8. During the night there was another hæmorrhage from the bowel, after which the patient became semi-conscious, dozing most of the time and complaining but little. Extremities and face cold. Pulse 150, weak; temperature 98°. Died at midnight.

March 9. Autopsy, ten hours after death. No blood in the dressings or in the cavity of the sac. The packing of the cavity is almost dry. The cavity of the sac has diminished to one-

quarter of the size at time of operation, partly by retraction of the walls, partly by filling in. After removal of the gauze, the placenta was found in place on the posterior wall of the sac.

The autopsy revealed an opening at the upper insertion of the placenta, between the sac and the transverse colon. This opening was so covered by the border of the placenta as to make the blood pass down into the bowels, and not out into the sac. The sac was of very different thickness in its different portions. On the anterior surface it was about one-quarter of an inch thick, corresponding to the surface where the fetus was covered with omentum, and consisted in fact, of the thickened omentum. The remainder of the fetal cavity was entirely surrounded by loops of intestines, small intestine and colon, and here the sac wall was extremely thin, in some places cobweb-like, in other places slightly thicker, and everywhere more or less intimately adherent to the wall of the intestine. These adhesions were the result of a plastic peritonitis commencing at the time of the primary rupture into the peritoneal cavity, and extending as the fetus increased in size.

The placenta extended from the posterior surface of the uterus, entirely filling Douglas' fossa, more than six inches upward to the transverse colon. The placental area of the sac was very thin in some places; so much so that it tore into shreds on even so slight a manipulation as that required for the removal of the intestines *en masse* during the autopsy.

Summary of History.—We find, in a patient 34 years old, who had had one child, child-bed being followed by pelvic cellulitis, and who was then sterile for eleven years, an extra-uterine pregnancy characterized by the following course:

In the eighth week after last menstruation, probable rupture of a tubal pregnancy, indicated by sudden pain and vomiting; that is, symptoms of peritonitis, lasting for ten days. In the sixteenth week a similar attack, less severe. In the nineteenth week another severe attack of peritonitic symptoms keeping the patient in bed for one month. In the fifth month she felt life. In the second week of the ninth month a moderate attack of peritonitis. At the end of the ninth month spurious labor and death of the child, indicated by cessation of fetal movements. In the fifth week after the death of the child, the placental souffle began to diminish, and two weeks later it had ceased entirely. Six weeks after the death of the child another severe attack attended with peritonitic symptoms. In the eighth week perforation of the sac into transverse colon. At beginning of ninth week, operation; death six days later from hæmorrhage through the bowel.

Remarks.—This case undoubtedly belongs to a class of cases consisting of an original tubal

pregnancy which secondarily becomes an abdominal pregnancy with the placenta and fetus located in the abdominal cavity. In the great majority of cases where a tubal pregnancy ruptures at the end of the second or in the third month, the fetus dies and disappears, and if the patient survives the hemorrhage, both fetus and placenta are removed by absorption. In a small proportion of cases after this rupture the development of the fetus is continued, and the placenta, still partially connected with the old site in the tube, keeps on growing and implants itself on the walls of the peritoneal cavity, from the small pelvis upward on the anterior, posterior or lateral abdominal wall. When the rupture has given rise to no symptoms of hemorrhage a plastic peritonitis takes place which quickly forms a barrier between the territory occupied by the fetus and placenta, and the remainder of the peritoneal cavity. The product of this plastic peritonitis is probably first a fibrinous exudate, later on organized into connective tissue which forms the so-called sac. This probably does not differ in any respect from the connective tissue layer found in the wall of any other localized or, as it is called, encapsulated peritoneal exudate.

As the growth of the fetus and placenta continues, more and more space is required, rupture of the sac occurs into a new territory of peritoneal cavity up to this time intact, and this territory is again limited by a plastic peritonitis resulting in an enlargement of the sac sufficient for the needs of its contents for some time. This procedure gives rise to symptoms of peritonitis, acute in its onset, but which gradually subside. In certain forms of purulent peritonitis we find a similar method of intermittent extension giving rise to successive attacks of peritonitis with free intervals between the attacks.

This mode of development makes it natural that the sac should vary in thickness and resistance in different parts. Thus we would expect to find it thicker in the space between two intestinal loops or between a loop of intestine and one of the viscera, than on the convexity of the wall of these organs. The greatest thickness of the sac will be found, as in this case, where the omentum has participated in its formation. This would naturally occur on the anterior surface of the fetal sac. The thinnest portion of the sac wall will be found on the convexity of the loops of intestine, and this is the place where rupture into the intestine takes place, either spontaneously or during attempts at extirpation of the sac.

In extra-uterine pregnancy where a uniformly thick sac wall is found, it is natural to suppose that rupture of the tube has not taken place, but rather a uniform dilatation. These are probably the cases in which one layer of the wall of the sac is composed of organic muscular fibres, and

in such cases, total extirpation of the sac is possible.

Entire absence of the sac, the fetus lying in the free peritoneal cavity between intestines which are not matted together with adhesions, is a rare occurrence. Such cases have, however, been described by King, Lawson Tait and Goetsch. In the case of Lawson Tait, the intestines protruded immediately after the extraction of the fetus through an opening made in the posterior cul de-sac of the vagina. In the case of Goetsch, at the time of laparotomy, a full grown child was found free amongst the intestines, but yet, strange as it may seem, fresh and not decomposed, although laparotomy was not performed until two years and a half after the spurious labor.

Symptoms.—I shall not enter into a consideration of all the symptoms of extra-uterine pregnancy, because these are to be found in the textbooks. There are, however, two symptoms in this case to which I wish to call attention, mainly on account of their prognostic significance; first, the repeated attacks of peritoneal irritation, and second, the final symptom of perforation into the bowels—the bloody diarrhea.

We notice in this case repeated, severe attacks of symptoms of peritonitis, so severe as to keep the patient in bed sometimes for a month at a time, and characterized by intense abdominal pain, vomiting and occasionally tympanitis. These attacks necessarily caused progressive loss of strength and emaciation, and thus the patient's condition became gradually less and less favorable for operation. In this class of cases early operation, irrespective of the condition of the child or of the placenta, would be likely to give a better prognosis for the mother.

The final catastrophe, perforation of the sac into the intestines, bladder or vagina, is characterized by a discharge of the liquid contents of the fetal sac, liquor amnii or pus; usually mixed with blood. Perforation into the intestinal tract is by far the most common, as the intestinal wall furnishes only slight resistance, and as a large area of the fetal sac must necessarily be formed of loops of intestine. Diarrhea, usually bloody, is the first symptom, rapidly followed by symptoms of sepsis due to microbic invasion of the sac. Rapid pulse and high temperature commence within twenty-four hours of the rupture. An especially characteristic symptom and one well marked in this case and caused by the entrance of gases from the intestinal tract into the sac, is tympanitic percussion over the area where formerly dull percussion was found. This symptom is of course absolutely pathognomonic of rupture into the bowel.

Rupture into the bowel is a common occurrence, as out of one hundred and thirty-two cases collected by Hecker, cited by Bandl, the fetus

was eliminated through the rectum in twenty-eight instances with recovery of the mother. It is not too much to assume that this condition was present in at least a corresponding proportion of the forty-four cases in which the mother died without an operation having been performed, as sepsis must invariably follow the perforation.

Prognosis.—The prognosis is always grave, varying in the older statistics between a mortality of forty-two and eighty-eight per cent. Hecker forty-two per cent., Kiwisch eighty-two per cent. Henic, eighty-eight per cent.

Operative treatment.—Asepsis in operation has recently given a mighty impulse toward the amelioration of the prognosis of this grave condition, and the successful results as regards saving the lives of the mothers has made the operations for extra-uterine pregnancy to be counted by hundreds during the last four or five years, while formerly they were only sporadic occurrences.

The greatest success is accomplished by the operation in the early months of pregnancy, but it must be acknowledged that operations at or near term are at present not nearly so dangerous as they were in former years. A strict line of distinction must be drawn between the operations in the beginning, and those toward the end of extra-uterine pregnancy. The two conditions, although only different stages of the same anomaly, present such vitally different anatomical conditions, chiefly on account of the difference in the size of the territory and the difficulty of the operation, that comparison is impossible. The early operation is technically no more difficult than the extirpation of the normal non-adherent uterine appendages; the operation toward the end of pregnancy, however, by which we mean the total removal of ovum and its contents, is always formidable and often technically an absolute impossibility.

Early in pregnancy, whether before or after rupture of the tube, which is almost always the primary seat of extra-uterine pregnancy, the operation presents no technical difficulties. The adhesions are slight or not present, for the tumor rarely exceeds the size of an orange or a large fist. Hemorrhage is easily controlled by ligation of the vessels of the broad ligament, which can always be found without difficulty. The prognosis of the operation is always good if the mother is in good condition; that is, is not exsanguinated by copious intra-abdominal hemorrhage from a previous rupture of the tube.

The operation in the latter half or at the end of pregnancy is usually formidable. The extirpation of a sac which often fills the greater part of the abdominal cavity, with adhesions to innumerable loops of intestines, the walls of the sac varying in thickness and consistency from that of tissue paper to quarter of an inch, together

with the danger of hemorrhage from a full grown placenta which may be divided by the incision into the sac, or if not divided may even by slight detachment at its border cause a gush of blood which would fill the sac in a minute; such conditions put to a most severe test the presence of mind of even the most experienced operator.

The considering the operation in the latter half of extra-uterine pregnancy we distinguish between laparotomy with living child, the so-called primary laparotomy, and laparotomy after the death of the child, the so-called secondary laparotomy. This distinction has no technical, but only a prognostic value for the child and mother.

From another point of view, we distinguish between the radical operation, removal of the whole of the fetal sac with its contents, child and placenta, and the non-radical operation or incision of the sac, a linear opening into the sac large enough for the delivery of the child, and the union of the borders of this incision with the opening in the abdominal wall. As regards this latter operation, we make a further distinction between the operations where the placenta is removed at the operation and those in which it is left to come away spontaneously later on, or as in very rare instances to remain in the peritoneal cavity, where it partially disappears by absorption, or may be transformed into a mass of cicatricial tissue, as has been observed by Goetsch and Braithwaite, on the outer wall of the uterus.

It is evident from what has been already stated that the radical operation is technically the most difficult one, for on account of the nature of the so-called sac, its total removal is usually difficult, and very often impossible. Thus the choice between incision and extirpation would require very serious consideration in the individual case, and the surgeon will often find himself in a very serious dilemma in this regard.

Thus in a number of instances, extirpation of the sac has been commenced, but after the operation has been partially performed the extirpation had to be abandoned on account of the impossibility of proceeding further. In such cases a part of the wall has been extirpated and part united with the abdominal wound; in other instances the connection of the sac with the uterus has made it necessary to amputate the latter, in order to accomplish the total removal of the sac. The advantage of the total removal of the sac, even if it involve so serious a complication as abdominal supra-vaginal amputation of the uterus, lies in the control of hemorrhage by ligation of the uterine arteries, and in the greater security against sepsis or intoxication from a non-removed sac and placenta.

The prognosis of the operation as given by the statistics from the literature up to date shows a remarkable decrease in mortality in the last five

years. Primary laparotomy was attended by a very great mortality up to the end of 1886. Thus, Werth reports eight cases with seven deaths, a mortality of eighty-five per cent.; Litzmann, ten cases with nine deaths, ninety per cent.; Harris, thirty cases with twenty-five deaths, eighty-three per cent. From 1887 to 1890 inclusive we find reported by Leopold Meyer seventeen cases with five deaths, a mortality of thirty per cent. This may be fairly considered as the present mortality of primary laparotomy for this condition.

Up to 1886 the mortality of secondary laparotomy was, as Litzmann states, to a great extent dependent upon the presence or absence of placental circulation. The operations before cessation of placental circulation had a high mortality. In ten cases in which the operation was done within the first five weeks after the death of the fetus there were eight deaths, a mortality of eighty per cent.; while later operations, from six weeks to a year after death of the fetus, had a much less mortality; Litzmann reports twenty-three cases with six deaths, a mortality of twenty-six per cent., and Werth, twenty-five cases with eight deaths, a mortality of thirty-two per cent. This great difference in the mortality led Litzmann to advise against operation immediately after the death of the fetus and to advocate delay until after cessation of the placental circulation.

For the last four years, the statistics of secondary laparotomy show a still better prognosis. Leopold Meyer reports seventy-two cases with twelve deaths, a mortality of only eighteen per cent. As far as can be observed, the secondary laparotomies during the last four years have not been performed with strict regard to the cessation of placental circulation. It is likely, however, that Litzmann's advice has caused many operators to postpone the operation as long as possible.

The prognosis of extirpation as compared with incision, so far as the statistics of the last four years enable us to judge of this question, shows very little difference in the mortality of the two operations. Thirty-six cases of extirpation, or the radical operation, have been reported, with six deaths, a mortality of sixteen and seven-tenths per cent.; and sixty-four cases of incision, or the non radical operation, with twelve deaths, a mortality of eighteen and seven-tenths per cent. Four cases were reported in 1890 of partial extirpation; that is, cases in which extirpation was attempted but could not be completed on account of the impossibility of freeing the sac, with two deaths, a mortality of fifty per cent. It will thus be seen from the statistics that incision has been performed nearly twice as often as extirpation.

In the non radical operation, incision, the question has been raised as to what should be done about the placenta, whether it should be removed or left *in situ*. The attempt to remove it

had its justification in the desire to obviate the danger of sepsis or intoxication from the considerable amount of dead tissue of the decomposing placenta. The danger of removing the placenta at the time of operation is on account of the difficulty or impossibility of controlling the hemorrhage from the sac of the placenta. It has been proposed that those who perform the radical operation should control the hemorrhage in one of the following three ways:

1. By previous ligature of the spermatic and uterine arteries before removal of the placenta.
2. By ligature *en masse* of the bleeding parts of the placental territory of the sac after the removal of the placenta.
3. By pressure from packing the sac full of sterilized gauze impregnated either with iodoform or with a mixture of salicylic and tannic acids.

Ligation of the spermatic and uterine arteries can be done only in cases where the broad ligaments are accessible. This is probably of comparatively rare occurrence, as in most cases in which the sacs are not well defined, the broad ligaments and uterus are hidden below the placenta.

Ligature *en masse* of the placental territory of the sac is extremely difficult and often impossible, partly because of the enormous hemorrhage from this territory and partly because of the danger of injury to the intestines if in close proximity to the bleeding placental site.

Pressure by packing the sac with gauze is unreliable, as we have to deal with a cavity which has no firm walls against which to make pressure.

The statistics for the last four years show twelve cases in which the placenta was removed, with four deaths, a mortality of thirty-three per cent.; and twenty-nine cases in which the placenta was left undisturbed, with five deaths, a mortality of seventeen per cent. Thus we may conclude that it is at the present time more safe to leave the placenta intact, as was done in the majority of cases, or at any rate, to limit the attempt to remove the placenta to those specially favorable cases where the afferent vessels can be found and secured before its removal.

Final Remarks.—The most important points to consider in extra-uterine pregnancy advanced beyond four months are:

1. When shall we operate?
2. And what operation shall be done?

The question of the time for operation cannot be solved merely by looking at the mortality from the statistics. The fate of the child I shall leave entirely out of consideration, as I believe that very few operators of to-day agree with Lawson Tait in weighing the life of the child against that of the mother.

The maternal mortality as seen in the statis-

tics, shows as stated above, a great difference between primary and secondary laparotomy, a difference of twelve per cent. in favor of the latter. Notwithstanding this, a number of modern operators are inclined to give up the secondary operation and operate as early as the diagnosis is made irrespective of the child or of the placental circulation.

Certain operators, such as Olshausen, Lawson Tait, Thornton, Werth, Lusk, Wilson, Doran, Hart, Martin, and others, advocate operating as early as possible. To explain this, notwithstanding the apparently greater safety of the late operation, there must be a fallacy in the conclusions drawn from the statistics. This fallacy is the following: A number of patients, especially those having recurrent attacks of peritonitis, will die either from peritonitis or from perforation and sepsis before the time for the late operation has arrived. If these cases of speedy death after rupture were included in the statistics of the mortality of the secondary operation, its percentage would be materially increased.

During extra-uterine pregnancy the mother is in danger all the time, from rupture with hæmorrhage and sepsis. It is impossible to know when this will occur and it has often been observed, as it was in my case, that rupture has taken place during the time of waiting, before the day set for the operation.

Rupture is always followed by sepsis, and an operation of necessity in the case of a septic patient has of course a bad prognosis. Sometimes even, death will come so suddenly that it would have been impossible to perform an operation, as in an instance mentioned by Harris in which the patient died half an hour after perforation had taken place.

It remains true that a number of extra-uterine pregnancies go through to full term without rupture or even after term for months or years; It also remains true that the longer after the death of the fœtus the operation is performed, the less is the mortality. But it is impossible to foresee in a given case whether or not the patient will escape rupture and sepsis. Hence the conclusion to operate as early as possible as a prophylactic measure. As early as possible means as early as the diagnosis is made, and this I consider to be the standpoint of to-day in this regard.

If the future repeats the history of the past we may confidently expect that the prognosis of the early operation will be still better than heretofore. Future clinical observations should enable us to make a differential diagnosis between two distinct classes of cases: The one, those in which perforating peritonitis does not take place and the patient is in no danger at any period before or after term; the other, those in which the patient is exposed to the dangers of perforation and sepsis at any time. When this stage of pro-

gress has been reached the late operation may again have a legitimate field.

The question of the choice between extirpation and incision is much more difficult. The almost equal mortality from these operations, as shown above in the statistics, helps us very little in this respect, as it does not indicate by any means an equal choice between the two procedures.

The radical operation, desirable as it is, as far as control of sepsis and hæmorrhage is concerned, can be done only in a limited number of cases where the sac is so uniformly strong and the adhesions so favorably arranged as to make this operation possible. In a large number of cases incision would have to be done as a matter of dire necessity, in cases in which the condition of the sac and extensive, short adhesions, especially to the intestines, have made extirpation impossible.

The choice between the two operations is much more difficult after the sac has been opened and the child delivered, for it is often impossible to determine whether an attempted extirpation can be finished or not. The unfinished operation, the so-called partial extirpation, has a mortality of fifty per cent.

A difficult radical operation will tax the skill of the most experienced operator to its utmost, and the attempt to loosen the sac from the intestines has in several instances resulted in multiple intestinal wounds followed by death from shock and hæmorrhage, and this result may follow too bold an attempt in this direction even during the operation. Slight manipulations of the sac have often caused such a formidable and sudden hæmorrhage from the placenta that further operating has been rendered well nigh impossible.

The future will have to decide whether rapid removal of the placenta, and hæmostasis after its removal, can be advocated as a justifiable and safe procedure.

The non-radical operation has the advantage of being easy of performance, of requiring only a slight amount of operating and of taking but little time. Thus it would seem natural that this operation should be preferred by less experienced operators in all cases.

The placenta should not be removed in the operation of incision excepting in those very late cases where it has been already detached and lies loose in the sac.

THE JENNER CENTENNIAL.

The Report of the Committee on the Resolution of Dr. J. M. Toner, to Consider the Propriety of Celebrating the Centennial of the Discovery of Vaccination, by Jenner, with the Opinion of the Members of the Committee.

In accordance with a resolution introduced at the forty-first annual meeting of the American Medical Association, at Nashville, a circular was sent out to the members of the Committee of the Jenner Centennial of the Discovery of Vaccination, by the Chairman, Dr. J. M. Toner, stating the resolution upon which the inquiry was founded, and sitting forth in a series, nine specific interrogatories, which are hereby appended:

Circular to the Members of the Committee of the American Medical Association on the Jenner Centennial of the Discovery of Vaccination.

"WHEREAS, It is fitting that the American Association should take proper notice of the Centennial of the Discovery of Vaccination, by Dr. Jenner, as a protection against small-pox, which will occur in a few years; therefore, to the end that due and timely consideration be given to the subject,

Be it Resolved, That the President of this Association be empowered to appoint a Committee, to consist of one physician of recognized ability from each State and Territory of the United States, to consider the whole subject and report a practical scheme which shall bring the century of the practice of vaccination in this country under review, and in such study secure the expression and cooperation of the medical profession residing in every part of our country, old and new, and report with recommendations as to the scope and methods to accomplish this, to the next meeting of this Association, for its consideration and adoption."

MY DEAR DOCTOR:—Under the preamble and resolution which heads this circular, the President of the American Medical Association has named the committee thus authorized, of which you are one. It is an agreeable duty for me to announce to you this fact (although the constitution of the committee has already been published in the Journal of the Association), and to solicit your earnest cooperation and advice in the matters submitted to us, that we may collect the views of each other by writing, as it is manifestly impracticable to have a meeting of the committee at which anything like a majority could attend; but by a correspondence, we may agree upon a report, based upon the views of a majority, to be submitted to the American Medical Association, at its next meeting, for its consideration and action.

With a desire to aid in taking a comprehensive view of vaccination, and the benefit which its discovery has been to the world, as well as how most appropriately the medical profession of the United States can express its gratitude to the memory of the great discoverer, and, at the same time, give unity to a line of thought in these directions, the following inquiries are formulated from the suggestions of the preamble and resolution creating this committee; and are submitted

for your consideration. As they embrace some of the more essential points of the project specific replies are requested to each of these inquiries, in their respective order.

But I entreat you to bear in mind that the whole subject embraced in the resolution is submitted for our consideration, and recommendation to the Association; therefore, take these queries only as spurs to reflection, and freely suggest whatever you may deem important, and which, in your judgment, will add interest and value to this, in many respects the most important event in the history of medicine.

Inquiry 1. Is it desirable and feasible for the medical profession of the United States to take special notice of the approaching centennial of the discovery of vaccination by Dr. Jenner, and if so, to do it in so considerate and thorough a manner as to give to the occasion a pronounced professional, scientific and historic character? If your judgment approves of the purposes indicated in "Inquiry 1," please give briefly the chief reasons which occur to you for such action on the part of the profession. Designate your answers to "Inquiry 1" *a, b, c, d, e*. But if your judgment be against "Inquiry 1," please give briefly your reasons for such a conclusion and designate them as No. 1, *a, b, c, d, e*.

Inquiry 2. If you approve the general proposition for a systematic observance by the medical profession of the United States, is it your opinion that the American Medical Association should dignify the occasion by providing for comprehensive reports on vaccination from all the States, and devote at least one day that year (say Thursday, during the annual session), for their consideration, embracing an eulogy on Jenner, and addresses and papers from special students on vaccination, and by the members of the Centennial Committee, or parties selected by them from the several states, with voluntary papers, etc., covering the practical, as well as the popular side in the history of vaccination in our own country during the century.

Inquiry 3. The approval of the general project of course carries with it the necessity of outlining with some degree of definiteness, the scope of studies and inquiries proper to be made, and which may tend to honor Jenner and redound to the credit of the profession of the United States.

In answering "Inquiry 3," you are requested to outline the scope and extent of the inquiries you would deem it desirable to have made. *a*, How and by whom collected? *b*, Is it best to have one person in each State responsible for the work in his own State, with such assistance as he may evoke to collect the data? *c*, Would you have the centennial services assume the character of a symposium, where each participant would respond to an assigned theme in a written report or paper, and thus cover the whole

field for each and every State, city and county in the Union? for the Army, the Navy and the Marine-Hospital Service? or *d*, would you centralize and ignore State lines, the Army, the Navy, etc., and speak in general terms for the country as a unit and a Nation?

Inquiry 4. Is it desirable, and would you advise, that an effort be made to collect as far as possible, all the facts relating to the history of vaccination in our country, and have them embraced in a history of the progress and practice in each of the several States, counties, cities and municipalities of our country, by forming committees in each, who should procure copies of all the laws and regulations which have once been in force, as well as the existing laws and regulations, whether advisory or compulsory in the several States and cities in the United States, the Army, the Navy and the Marine-Hospital Service, to be embraced in a report to be made by the Jenner Centennial Committee to the American Medical Association in our centennial year.

If you approve of "Inquiry 4," please give briefly the chief reasons for your conclusions, and record them as No. 4. *a, b, c*.

If you disapprove "Inquiry 4," please give briefly the reasons for your conclusions, and record them as No. 4. *a, b, c*.

Inquiry 5.—Is it practicable, and, if practicable, would it, in your opinion, be of historical value to the profession to collect, as far as possible, copies of all documents and publications which have been in any way connected with vaccination, whether appearing in book form, pamphlet, report, newspaper, journal, broadside, etc., which have appeared in any State or city in the Union since the discovery of vaccination? *a*—Where printed copies cannot be had should manuscript copies be made; or, *b*, exact titles of them, when and where printed, be made?

If you approve of "Inquiry 5," please state the chief reasons in its favor and record them as No. 5. *a, b, c, d*.

If you disapprove of "Inquiry 5," please state chief reasons for such conclusions and record them as No. 5. *a, b, c, d*.

Inquiry 6.—Is it desirable to have a wide discussion on the practical, as contra-distinguished from the historical, side of vaccination in the proposed Centennial, to include the most approved methods to secure the fullest benefits of the operation?

a—The advantages of bovine virus over that which has passed through the human system:

b—The cause of alleged failures of vaccination to protect against small-pox:

c—The advisability of compulsory laws to secure general and universal vaccination:

d—And, in view of the fact that disparaging remarks are occasionally made and published by people of education and influence, should we not,

in the most positive and unqualified manner, declare our confidence in bovine vaccination as a complete protection against small-pox? What other subjects would you admit to the discussion?

If you deem it desirable to have the practical side of vaccination discussed, please give briefly the chief reasons in its favor and record them as No. 6. *a, b, c*.

If you deem it inadvisable to discuss this practical side on such an occasion, assign the chief reasons which present themselves to you and record them as No. 6. *a, b, c*.

Inquiry 7.—From your acquaintance with the medical gentlemen of your State, what, in your opinion, is the best method of engaging their hearty cooperation in collecting such information as will make the proposed Centennial of Jenner's great discovery at once an ovation to his memory, a credit to your State, and a benefit to the medical profession of America?

Here give your views as to the efficiency of the cooperation which may be expected from proper applications to your organized medical societies, State, county and city.

b—Make suggestions as to any method of obtaining the historical data for your State which may occur to you.

c—Have you one or more authors or experts on vaccination whose appointment on a committee would command the confidence of the profession of your State and secure the cooperation of their medical brethren?

d—Should the committees to collect data in the several States consist of one or more members?

Inquiry 8.—Unfortunately, State Medical Societies do not exist in all the States, nor do local societies exist in all the counties in those States where there are State Medical organizations, although the theory on which the American Medical Association is formed, contemplates the county medical society as the unit of organization, whose delegates shall constitute and form the State Medical Society. Where County Medical Societies exist, should they in every case be applied to for aid? To what extent, in your opinion, can these be relied upon to cooperate in the collection of the data required for the reports suggested?

Here express your own views, and for your own State.

Inquiry 9.—Where County Medical Organizations do not exist, and where existing County Medical Societies fail to cooperate when requested, what expedient can be adopted to secure from these localities the data required?

To meet such contingencies, would it be expedient and desirable to have lodged with the Chairman of the General Centennial Committee the power to appoint one or more reputable physicians as a committee in such counties to furnish the desired information?

Give your view of the desirableness of the power asked for in this "Inquiry 9." As a member of the committee, volunteer whatever suggestions you think may serve to dignify and make profitable the proposed Centennial of the discovery of vaccination, and secure the compilation of as complete a history of the beneficence of its practice in the United States as practicable.

You are earnestly requested to give to this subject an early consideration. A want of uniformity in responses, with the new and valuable suggestions not here presented or as yet thought of, will require much correspondence, and the repolling of views so as fairly to embrace the judgment of the majority of our committee in a report.

You are particularly requested to number your responses to all inquiries as suggested, so as to facilitate the work of tabulating the views and recommendations of the several members.

Mail your answers to DR. J. M. TONER,

Chairman of Committee of American Medical Association.

615 Louisville Ave., Washington, D. C.

Replies were received from twenty-two States, as follows: Alabama, Connecticut, Delaware, District of Columbia, Florida, Indiana, Iowa, Illinois, Kentucky, Kansas, Maryland, Missouri, Michigan, Minnesota, Massachusetts, Nebraska, New Jersey, New Hampshire, North Carolina, Ohio, Pennsylvania, Wisconsin and Virginia.

Your Committee have thought best to present the substance of the replies which have come in from the different States, in order to place the matter fairly before the Association.

Reply to Inquiry 1.—"Is it desirable and feasible for the medical profession in the United States to take special notice of the approaching centennial of the discovery of vaccination by Dr. Jenner?" etc., was answered in the affirmative by Alabama, Connecticut, Delaware, District of Columbia, Florida, Indiana, Iowa, Illinois, Kentucky, Kansas, Maryland, Michigan, Missouri, Minnesota, Massachusetts, New Hampshire, New Jersey, North Carolina, Ohio, Pennsylvania, Virginia and Wisconsin, the language of each being emphatic in tone, as a few extracts will show:

Dr. Jno. R. Quinan, of Maryland (since dead) writes: "A centennial celebration of the discovery of vaccination is highly desirable, *a*, as an evidence of our grateful remembrance of Jenner; *b*, as an additional proof of our entire and abiding confidence in the efficacy of vaccination; *c*, as a means of calling the attention of the public to its advantages, and teaching it anew the lasting and inestimable debt it owes to our profession in the discovery of the greatest boon ever offered to the human race."

Prof. C. A. Lindsley, of Connecticut, says: "The recognition of the discovery of vaccination at its centennial anniversary has my most hearty approval, *a*, because it has contributed more to the welfare of mankind than any other discovery; *b*, because it is justly due to the great discoverer that the lustre of the name of Jenner be made to shine, that all men may pay it deserved homage; *c*, because in these days of centennial celebrations, an omission would be discredit to our profession, and would give encouragement to those aberrant and erratic minds who would defame Jenner, and deny the value of vaccination."

Dr. Jno. P. Ware, of Florida, says: "... it is desirable

to take special notice of the approaching centennial of Jenner's great discovery, May 14, 1806, *a*, as honoring the memory of a great man and a noble philanthropist; *b*, to give renewed public confidence in the prophylactic virtue of vaccination, in refutation of the teachings of the anti-vaccinationists; *c*, for the purpose of convincing the public of the mischievous writings for the public of Dr. Chas. Creighton in the *Encyclopædia Britannica* and in the *Acena* magazine."

Dr. Jas. F. Hibberd, of Indiana, says: "Yes, it seems both desirable and practicable for the profession in the United States to take special notice of Jenner and vaccination at the centennial of his discovery. *a*, It will be a suitable and favorable time to freshen up the subject, and impress the people of this country with the nature and value of vaccination; *b*, Dr. Jenner's memory should have distinguished consideration for the acumen that led him to discover vaccination, and for the courage with which he wrought out the problem to a demonstration in the face of great discouragement; and Americans should do this honor as testifying to their appreciation of the imperishable fame that attaches to the name of Jenner, and at the same time constituting an expression of American admiration for pluck, and as an encouragement to young scientists who may encounter similar stumbling-blocks."

The only qualified approval was from a distinguished student of vaccination in New York, who believes "it would be better for the American profession to coöperate with their colleagues in other countries than to celebrate on their own account."

Reply to Inquiry 2.—"If you approve the general proposition for a system of observance by the medical profession of the United States, is it your opinion that the American Medical Association should dignify the occasion by providing for comprehensive reports?" etc. All the reporters agree with the general proposition, except that a few think three days little enough time to devote to such a great question. The late Dr. Quinan, who is among this number, says: "While heartily endorsing the efforts of the American Medical Association in this regard, I do not think one day sufficient to do justice to any programme of exercises at all worthy of the occasion. Three days at least ought to be devoted to it. The first day's exercises should embrace the history and literature of vaccination, including eulogies on the life and labors of Jenner; of Waterhouse, of Massachusetts, Seaman, of New York, James Smith and others of Maryland, J. R. Cox, of Philadelphia, Dr. Gantt, of Washington, Dr. Wardlaw, of Virginia, Dr. Ramsay, of South Carolina; a report on the literature of vaccination; the statistics and scientific aspects of vaccination. The third day to be devoted to papers on the practical results and blessings to the public."

Report on Inquiry 3, as to the "scope and extent of the inquiries you would deem it desirable to make," etc.

Maryland would select a representative man from each State to collect the data required, except where the small size, contiguity of territory and similarity of history in regard to vaccination admits of grouping them; hence he would have but one appointee from New England, one from New Jersey and Delaware, one from District of Columbia, but one for the territories, and one from the Pacific States, the other states should have one each.

Alabama "Suggests one able and competent person collect the data wanted with the assistance of one person in each State. Thinks there should be only one person from a State, and that it would be desirable to centralize and speak for the country as a unit," etc.

Wisconsin thinks a committee from each State would be advisable, and the experts might be invited to prepare papers; would centralize and treat the whole country as a unit.

Ohio thinks the scope of enquiry might be modified by the character of the investigation being made by the

Royal Vaccination Commission, Great Britain; not advisable to follow in their track.

Massachusetts: A eulogy on Jenner and reading of papers on different phases of the question by special students of vaccination. Special students should prepare papers—these being selected by the committee or being volunteers approved by the committee.

North Carolina: The inquiries should be historical, statistical and scientific.

Pennsylvania thinks that every phase of knowledge of vaccination should be inquired into. The prophylactic power; the duration of protection, and the value of re-vaccination; the unfortunate results of vaccination and how to guard against them; the relative value of bovine and humanized lymph; a discussion of the question whether or not could vaccination be made more general by a compulsory law.

New Jersey: Dr. Ezra M. Hunt, N. J., answers yes! "That the claims of Jenner to recognition are being disputed by those of scientific and professional reputation, and that this dispute involves the whole subject of vaccination."

"The article of Dr. Creighton in the *Encyclopædia Britannica*, his utterances since, his testimony before the parliamentary commission that vaccination is of no value; the two wonderful volumes of Prof. Crookshanks and his concurrence in this opinion, and the position of the anti-vaccinationists generally is such that however much we assert, their views must be met by facts and counter evidence."

Investigation should be made by State Medical Society, State and city boards of health. The headships of committees should be given to one who has time and accurate capacity, not for long rhetoric or long essay, but collective investigation with authorities attached. The best evidences of the value of vaccination in its best form, by a full committee formed of the chairman of the local committee named, who in order for success should have for a year or more a paid secretary.

Michigan: Would have one person to summarize in general for the country as a unit and a nation.

New Hampshire: Thinks the investigation and the history of the introduction into the United States should be by one man.

Missouri: Thinks that the question as to the nature of the investigation may be best left to a central committee, but that to secure system and coherence the same committee should direct the preparation of assigned themes, reports, etc.

Kansas: Physicians should be appointed to the work. Definite topics should be assigned to those selected, that the whole ground may be covered and repetitions avoided. States might be dealt with individually and a member might be selected from Army, Navy and M.-H. S.

Virginia: Would select the State Vaccine agent, where there is such an officer to be chosen of State committee on Centennial. Would not require State lines in the inquiry.

Kentucky: Would entirely ignore State local lines and limits. Has little confidence in the attempt to gather statistics from various States and smaller political divisions.

Iowa: Would have a committee from each State collect data presenting condition of laws regarding vaccination, and make arrangements for a general address by a speaker by them selected.

Delaware: Would be desirable to condense and tabulate all facts and papers received, on history of the discovery, benefits derived from it, necessary legislation required to make it effective.

Indiana: Scheme should embrace a succinct history of the use and progress of vaccination in England, and in a general way the world over. When its introduction spread over the United States. All of this should be conducted under the superintendence of one person thoughtfully selected by American Medical Association.

commissioned to select his own advisers and assistants.

New York: Would centralize and ignore State lines, the army, the navy, the marine hospital service, and speak in general terms for the country as a unit and as a nation.

Connecticut: The work could be best done by a small committee, yet in large States a different plan might be preferred. Vaccination applies to all mankind.

INQUIRY 4.

"Is it desirable . . . that an effort be made to collect as far as possible all the facts relating to the history of vaccination in our country . . . by forming committees in States, counties, cities, etc.?"

Connecticut: It would make a large library.

New York: Would be exceedingly bulky and of little value.

Indiana: It would be impracticable to get material for each county, etc. Would be a waste of time and hunt for two grains of wheat in two measures of chaff.

Alabama: Impracticable to embrace much minute matter in the report.

Michigan: Would not deal with counties or cities except a few of the largest.

New Hampshire: For the purpose of historical preservation research should be made, but by one man.

Missouri: Desirable to have the history but don't know if it is practicable. Would make the effort.

Kansas: Thinks it ought to be done.

Iowa: Would make a memorial volume, and let committee control the content.

Delaware: It would be desirable to condense historical matter.

North Carolina: Thinks it desirable to make the historical research.

Pennsylvania: Approves of the research but advises no printing tedious details.

New Jersey: Would by all means make the effort.

Virginia: Thinks as it is a historical commemoration that all the historical facts should be collected.

Massachusetts: A general history of vaccination should be obtained for this country.

Ohio: Thinks it desirable to collect a sufficient number of data to establish the history and nature of the laws.

Wisconsin: Don't think it would be practicable to collect details.

Maryland: Thinks that historical data should be collected and sets forth the heads of subjects to be investigated historically.

INQUIRY 5.

"Is it practicable to collect books and documents," etc.

New York answers negatively.

Maryland does not think it practicable.

INQUIRY 6.

"Is it desirable to have a wide discussion on the practical as contradistinguished from the historical side of vaccination?"

New York thinks it would not be profitable.

Maryland thinks it would if judiciously done, etc.

New Jersey thinks discussion will be desultory.

North Carolina thinks it not well. The well informed would agree, but the erratic might make it a time to air hobbies of anti-vaccination.

INQUIRY 7.

"From your acquaintance with medical gentlemen of your State, what is the best method of engaging their hearty cooperation?"

Kansas: "By personal application and through local State Societies they will all cooperate mildly. Give one charge of the work, with power to appoint assistants."

Delaware: "thinks through local societies."

Iowa: State Medical Society is an active body. He knows of no experts in Iowa. Knows a hundred scientific physicians who would give their experience.

Kansas: No available statistics. Give one person charge.

Missouri thinks the general profession will take little interest in it. Facts can only be had by enlisting clerks of Boards of Health and engaging the interest of secretaries of reputable vaccinologists.

New Hampshire:—Very little information outside of the brief history of introduction could be obtained from New Hampshire. No one has given special attention.

Michigan:—"Has an impression that the Committee does not need the cooperation of the practitioners in general of that State, but the careful painstaking of the few, perhaps not more than one or two in each State."

Indiana:—"There would be an uncertain amount of good material obtained through the State Medical Society; best results would be obtained by submitting it to the consideration of County Societies through State Societies. He knows of no expert in Indiana. Best results would be obtained by committing the affairs in each State and Territory to one competent person, who would work under a plan formulated by a chief."

New Hampshire:—By circular letters submitted to such members of the profession as would be most likely to be interested and render active assistance.

Alabama:—"The State Board of Health of Alabama is the proper source from which to gather all necessary matter."

New York:—"I would deal with individuals and not with societies, to one man in each State; in New York to the Surgeon General of the State."

New Jersey:—"Knows of no man who could be called an expert, but selection could be made by the State Medical Society of the best persons for the purpose."

INQUIRY 3.

"Where County Medical Societies exist should they in every case be applied to for aid?"

This query is answered mostly under 7th inquiry.

INQUIRY 6.

"Would it be expedient and desirable to have lodged with the Chairman of the General Centennial Committee the power to appoint one or more reputable physicians as a committee in such counties to furnish the desired information."

North Carolina:—"It would be best to invest a Central Committee with the function of making selections of the fittest men for the work by consultation with the State, county, city medical organizations and with medical librarians, or others acquainted with acquirements of medical scholars."

New York:—"Thinks data would be useless, therefore does not advise means to collect them."

Indiana:—"The Chairman in chief of the General Committee should be empowered to make appointments such as alluded to in this inquiry and should also be authorized to delegate this power of appointment to others where in his judgment it would further the purpose of the undertaking."

Connecticut:—"Give the Chairman of the General Committee power."

Missouri:—"Believes that power to appoint should be vested in the general chairman."

Alabama:—"Would suggest the appointment of one man in each State and allow him to exercise his own preference in gathering data; and the State reporter could draw upon any physician he wishes as an individual."

Kansas:—"The general subject is put in the hands of Centennial Committee. It is impracticable to have meetings; is entirely willing to impose upon the Chairman such members as he may call to his assistance."

New Hampshire:—"Let the men appointed to read papers do it entirely in their own way, and let them be responsible for their work."

Delaware:—"Where there are no societies the duty might fall on health boards, college faculties, or eminent members of the profession."

Iowa:—"In the event of no societies, he would call on individuals."

Pennsylvania:—"Would give Chairman of Centennial Committee power to act, adopting any means he sees fit to collect information from any State or territory."

Virginia:—"Better to leave the appointment of the best men for the work to a State Committee or State Medical Society."

Florida:—"Think it would be well to leave it to Chairman of Centennial Committee to appoint."

Massachusetts:—"It would be best to leave to Centennial Committee Chairman."

Ohio:—"Let the Centennial Committee appoint in each State and territory a State Committee of three and where there is a State Medical Society appoint the Secretary or President of Society a member of this committee. Let the State Committee appoint a committee of three in each county, and where a county society exists appoint the President or Secretary a member of the committee, etc., etc."

Committee from American Public Health Association.

OUTLINE OF CONCLUSIONS FROM THE WHOLE MASS OF REPORTS.

1. The members of the committee are nearly unanimous in their opinion as to the appropriateness of the celebration of the centennial of Jenner's discovery. 2. That the celebration should embrace the collection of historical and statistical reports with a proper eulogy of Jenner and his work. 3. As to the scope and extent of the inquiries desirable to make there was some diversity of views, and some difference of opinion as to the value of the collective reports when made. 4. As to the effort to collect as far as possible all the facts relating to the history of vaccination in our country by forming committees in State and county societies, it was the general opinion it would be impracticable to embrace the minutiae of the past and present of vaccination. 5. The practicability of collecting books, documents, etc., pertaining to vaccination was answered by nearly all negatively. 6. As to the desirability of having a discussion on the practical as contra-dis-

tinguished from the historical side of vaccination, it was generally conceded that it would not be profitable. 7. As to the prospects of obtaining material through local and State societies, the question was answered affirmatively or negatively, according to the activity of the societies in the locality in which the reporter lived. 8. Should county societies be applied to for information where they exist is answered mostly in the previous enquiries. 9. Most of the committee were of the opinion that to the Chairman of the Centennial Committee should be left the appointment of the man or men, and devise the plan for the general work of the preparation for the centennial.

It was deemed proper, therefore, after this consensus of opinion as to the feasibility and propriety of celebrating the centennial of the discovery of vaccination by Jenner, to set apart the *17th day of May, 1896*, for the proper commemoration of the life work of Jenner, and signalize the immense gift which vaccination has been to the human family by the presentation of an eulogy of the great discoverer, and by the reading of specially prepared papers on the history of introduction, statistics, practice of vaccination, propagation of vaccine virus, and such other topics as may be selected by the committee.

In order to carry out this design, it is hereby recommended: 1. That the meeting of the American Medical Association be so timed, if possible, as to include the 14th day of May. 2. That the Central Committee on the Centennial Celebration should make such selections of persons, through the assistance of State, county, and city medical societies, medical college and medical and other librarians, as to constitute a corps of collaborators to work under the general guidance of the Committee. 3. That this Committee should select an eulogist, to deliver such a tribute to the life and work of Jenner as would be suited to a popular audience. 4. That an editor and compiler should be chosen by the Committee from the expert vaccinologists in the United States, upon whom shall devolve the work of digesting, compiling and preparing all the collected material, and that all the literary and scientific part of the work shall be under his direction. 5. That such material as the Committee deemed best should be collected and printed in a sumptuous volume, with appropriate illustrations. 6. That the editor and compiler should be allowed a clerk for such part of the time as he may be needed, not to exceed \$200 a year. 7. That all the preparation of the details of the celebration should be under the management of the Central Committee or their successors.

In presenting this provisional outline of the plan for the celebration proposed, the Committee desires to impress the Association with the greatness of the undertaking, and bespeak the hearty

cooperation of every organized society represented in this body. Your Committee would add, that the American Public Health Association, by formal resolution at their meeting last December, in Charleston, selected a committee to confer with this Association upon the proper plan for the celebration of the great event.

NEW INSTRUMENTS.

AN AUTOMATIC TUNING-FORK HAMMER.

BY S. S. BISHOP, M.D.,
OF CHICAGO.

The automatic tuning-fork hammer shown in the cut is for the purpose of making the fork as accurate an instrument for testing the hearing as the watch is, and especially for use in those cases where the watch is useless.

The hammer and operating springs can be attached to any large fork an aurist may happen to have. The hammer-head is made of soft rubber, so as not to require too large a room for its use.

In determining the hearing distance the same rules are observed as in using the watch. The ear is gradually approached from a distance, with the fork vibrating, until the patient, with eyes closed, signifies that he hears it. This experiment is repeated until we find by measurement the exact distance at which he hears it each time. Every time a sound is produced the hammer-handle should be pressed down to touch the fork-handle, so that, as it is allowed to slip from under the pressing thumb or finger, the hammer-head strikes the fork with an unvarying blow.

One of my forks can be heard 8 feet in a quiet room. I refer now to the musical note. The other sound that always accompanies a blow, and which we will call the dull percussion sound, can be heard in the same place 16 feet by a normal ear.

Taking this as an example in one of those numerous cases in which the watch cannot be heard, if the musical note can be perceived at 30 inches, we can express the hearing distance approximately correctly by the fraction $\frac{1}{100}$, or 30 per centum of the normal, showing a loss of 70 per centum.

There are not a few instances in which I have found no perception of the musical note, except on contact of the fork with the mastoid process, when the dull percussion sound was distinctly heard at a certain distance. This distance is easily ascertained by causing the patient to keep his eyes closed during the test, and to raise the hand at every stroke of the hammer he hears.

The proportion of hearing power lost and finally regained can be accurately determined by these

careful experiments. They eliminate the inaccuracies of the ever-varying quantity and quality of sounds emitted by the ordinary fork when struck on objects of differing density with varying degrees of force.

It is impracticable to record unerringly the

hearing distance by means of the voice. The watch-sounds are often not perceived at all, and the best instrument of precision for this purpose is the tuning-fork, so constructed as to produce sounds of unvarying volume and pitch.

In devising this accometer I do not claim for it any new principle—simply the practical application of very old ones to convert an uncertain instrument of diagnosis into an accurately reliable one.

After considerable experimenting with different materials and devices, and after using these forks in clinical work for some time, I have come to look upon them as indispensable for precision in aural practice.

They are made by Charles Truax, Greene & Co., of Chicago.

TOPICS OF THE WEEK.

ARE ANATOMY AND PHYSIOLOGY LIBERAL STUDIES?

At a recent meeting of the Board of Overseers of Harvard College a supplementary report of the Special Committee on Changes in the Academic Department and in its relations to the professional schools, was under consideration, and certain propositions offered by this Committee were voted on. Two of these propositions especially concerned medical education, namely:

That the Board of Overseers recommends the modification of the present Regulations of the College Faculty in accordance with the following proposition:

That a Senior intending to enter the Medical School and to take the full four-years' course therein may, under proper supervision, include in the requirements for the degree of Bachelor of Arts the courses on physiology and anatomy required in the first year of the Medical School, each of said courses to count as one full elective course.

That, in the opinion of the Board of Overseers, it is advisable that the Faculty facilitate the attainment of the degree of Bachelor of Arts, upon petition, in less time than four years, especially by those students intending to take professional or graduate courses of study, by means which do not involve either a reduction in the number or difficulty of the courses required for the degree, or an undue hurrying of the students' work.

Both of these propositions were rejected by the Overseers, the former by a vote of five to eighteen, the President of the University voting in the negative, and the latter by a similar vote, the President voting in the affirmative.

It is not the province of this Journal to question whether these proposals were voted upon strictly on their merits by the Overseers, or whether, owing to their relation to other proposals, regarded by some as kindred, they shared a common fate. It is, however, legitimate for us to speculate whether such a vote fairly represents the tendency of thoughtful sentiment to-day among college-bred men and among our educated communities, in

regard to professional studies and professional schools. We find it difficult to believe that it does.

The present relation of professional studies, and especially of medical studies, to an academic course, is concisely given in a short article entitled: "Is the Study of Medicine a Liberal Education?" by Prof. D. W. Cheever, of the Harvard Medical School, published in our last issue. It is very difficult to comprehend the mental attitude of one who, in the latter part of the nineteenth century, is unable to regard such studies as anatomy, physiology, or constitutional law as, in the widest acceptance of the term, "liberal" studies. Latin, Greek, Mathematics and Hebrew may equally be regarded as "bread and butter" studies for men who become teachers or clergymen. Chemistry and Physics and Political Economy are certainly such studies for a large number, if measured by any "liberal" estimate.

The truth is, some way must be found to lengthen rather than to shorten professional education, and especially medical education. The medical graduate with an academic degree is already too old, and it is plain that if young men cannot be liberally educated on such studies as those we have mentioned, many of them, if modern social life follows its present directions, must be illiberally educated without some of those studies which have hitherto claimed the title of "liberal" by right of inheritance.—*Doston Med. and Surg. Journal.*

THE INFLUENZA OF 1860 AND A DEPRESSED TONE OF HUMAN VITALITY.

In our Edinburgh correspondent's notes last week interesting extracts were given from the report submitted by Dr. Clouston upon the Royal Edinburgh Asylum for the past year. They had reference more especially to some evidence produced by Dr. Clouston as to the existence of an exceptionally low tone of human vitality during the year 1860, in relation to the epidemic of influenza. Whether it was the influenza in the early part of the year that had perceptibly lowered human vitality, or whether the prevalence of the influenza merely showed that European humanity was in a lowered state of vitality, so being a fit nidus for the influenza germs to propagate in, or whether it was the sunless, summerless general character of the year, Dr. Clouston could not not say. He distinctly connected, however, the influenza in some way with the unprecedented number of melancholic patients sent to Moruingside Asylum. He goes on to say, and we think with truth, that he believes the epidemic of influenza left the European world's nerves and spirits in a far worse state than it found them, and that they scarcely yet had recovered their normal tone. Many others have expressed themselves in the same sense, and we look upon the subject as one of deep interest. An excellent opportunity will be given our asylum superintendents, at this season of preparation of their annual reports, to confirm or otherwise this expression of opinion on the part of Dr. Clouston.—*Lancet.*

THE PROVINCE OF WOMAN IN MEDICINE.

MR. LAWSON TAIT is reported to have said: "For the greater part of my life I have been engaged in the study of and practice amongst the special diseases of women, and no conclusion is more firmly rooted in my mind than a devout thankfulness that I belong to the other sex." "From the cradle to puberty they seem to be on fairly equal terms with men, but from that moment, through the whole of the period of active life, their existence is one of prolonged suffering." "The great function of their lives is led up to by troubles, and from it endless suffering springs."

Such a view—and such expressions—from one whose life work has made him so thoroughly acquainted with the subject of the sexual characteristics of the female, must receive the consideration which is its due, and from it may be drawn conclusions and arguments which a less authoritative basis might render fallacious, or, in given directions, sentimental.

Although we do not propose to enter into this subject from the many different points of study it clearly permits, and which would quite fill a volume—yet there is one medical aspect to which the professional mind may briefly turn, and which constitutes one of the living topics of the hour, namely, woman in medicine.

Two arguments, based upon LAWSON TAIT's exposition, at once present themselves: 1. Can an unfortunate, pain-afflicted woman ever occupy a sphere of unquestioned usefulness in medicine,

where physical and mental vigor, fortitude, and endurance are eminently requisite, and where the strong must help the weak, help them by virtue of their strength, to healthier and stronger states? or, 2. Can the power of sympathy—operating from the intelligence of affliction, and the possible comfort of relief—together with knowledge and discrimination, pass from a medical woman to her suffering sex with a probability of extenuating their distress equally as great as would maintain under the fulness of power mentioned in the first proposition?

Such is the question, the argument of which has been before the medical profession for some time, but the solution of which may not be said to have as yet been reached.

This much remains clear, however, woman has yet to achieve any greatness in the ranks of medicine, and if such is to be her future portion it must be in the direction of relief to her own sex. She must become a LAWSON TAIT, a SPENCER WELLS, a BATTEY, THOMAS, PRICE; or if that be impossible, under the outlines of the first great general question, and the conclusions of LAWSON TAIT, then must she rest, in the unsought weakness of her nature, as a follower of man, and under the privilege of that sympathy which, if properly fortified, may reach, if not greatness, that degree of usefulness the medical world cannot, with reason, gainsay.

THE RELATION OF THE COLUMBIAN EXPOSITION TO THE MEDICAL PROFESSION.

Or it might better be said: The value and opportunities afforded by the World's Fair to the profession of medicine. It amounts to quite the same, however, whichever way it is put.

Physicians from all points of the compass, and from the most remote corners of the earth, will be attracted to the United States, to the City of Chicago, to the home of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

These facts force thoughts of the vast opportunities thus offered for the realization of many long-expressed desires, for the establishment of needed reforms, and for the opening of those paths to a broader knowledge, and a closer touch of interests, which this day and age demands.

1. The proposed Pan-American Medical Congress. It is contemplated to hold this meeting

during the World's Fair, and from its success we may look for many important considerations, such, indeed, as a representative body of this nature may pertinently and wisely sit upon.

2. The untold advantages for personal improvement and a knowledge of the great advances made in all branches of the science of medicine. This will come from the exhibitions, from study, from contact with others, and from the proximate seats of learning which may be easily visited.

3. The teaching of the period, aside from the results already attained, and upon which the great future progress is to rest. Methods of medical teaching will be particularly interesting to foreigners, and many of our own older practitioners who have been secluded for years by the constraints of a rural constituency.

4. The scope, usefulness, and grand possibilities of the American Medical Association. A duty and an opportunity obviously rests here, which in due time will no doubt be developed and formulated.

5. The contact with fellow laborers from every clime, and the mutual good which follows the free interchange of views and experiences. This communion of thought is the bulwark of our science, and its strengthening, upon this occasion of the World's Fair, will not be without happy results.

In a brief notice we can only hope to generalize the advantages promised. From time to time, however, we trust to speak of progress in this direction, and to dwell more specifically upon matters *à propos*.

VESICAL NEOPLASMA AND THEIR REMOVAL.

DR. GUYON, in the *Gazette des Hôpitaux*, reports a case of neoplasm of the bladder, in a male aged 30, and its removal by supra pubic operation. He presents some useful considerations in regard to the diagnosis and treatment of vesical tumors. Positive diagnosis by means of the endoscope should be considered of the first importance. The symptom of hæmaturia is inconclusive as an aid to the diagnosis of the size or character of the tumor, since a comparatively small papilloma will often give rise to a very considerable hæmorrhage. The supra-pubic operation seems to him to offer the best advantages in the ablation of tumors of this class. After the incision has been made and the tumor located

the latter should be seized by means of two hook-shaped forceps and brought into view as well as possible. The pedicle of the tumor excised along with a portion of the subjacent bladder wall. Dr. Guyon does not advocate the complete suturing of the bladder at the point of the supra-pubic wound, but favors the introduction of a drainage-tube at both ends of the incision and the suturing of the intervening portion. The writer has not found that the integrity of the resulting cicatrix is interfered with by this method of dealing with the surgical wound.

EDITORIAL NOTES AND ITEMS.

NEW EMERITUS PROFESSORS.—The intelligence was chronicled not long since of the cessation of the active labors of those two brilliant men in medicine, Drs. Bartholow and Da Costa, and now comes the news of tribute due them—election to emeritus professorships—under which, with greater leisure and unrestricted facilities, they may yet pursue those studies from which the world has derived much benefit.

INEBRIETY LEGALLY DISQUALIFIES THE PHYSICIAN.—The Secretary of the State Board of Health of Iowa announces that he is convinced that habitual drunkenness constitutes "palpable evidence of incompetency," as the law reads, and that therefore the physician bound by inebriety should be shorn of his certificate entitling him to practice in that State.

INFLUENZA IN ENGLAND.—This disease, which has been reprevailing throughout the British Islands, is now reported to be somewhat on the decline. The epidemic has been particularly severe and widespread, and as here, received much attention from the medical and lay press. Theories are advanced, and forms of treatment recommended; but there yet remains much to learn regarding this somewhat remarkable affection.

Late reports are that the disease is just touching certain points in France.

THE PRE-CONVULSIVE PERIOD IN PREGNANCY.—Dr. Everard H. Richardson, of Atlanta, Ga., declares (*Atlanta Medical and Surgical Journal*), the following rule: "In all cases of pregnancy, whenever albumin in the urine is persistently found in large quantities, with or without the

presence of any variety of casts, and not yielding promptly to treatment, *whenever decided symptoms of profound uræmia appear and continue unabated, then I unqualifiedly recommend and advise, as the safest course to be pursued in the interest of the mother, the induction of labor.*"

COUNTING TUBERCLE BACILLI.—In the last issue of the *Bulletin of Johns Hopkins Hospital*, G. H. F. Nuttall, M.D., gives an improved method for "the estimation of the actual number of tubercle bacilli in tuberculous sputum." The plan is illustrated and carefully worked out; the author maintaining: "With such organisms as the tubercle bacillus, this method will enable the experimenter to determine the number he is inoculating into an animal in a way that has not been possible hitherto. Inoculations under such conditions will clearly show the difference in degree of virulence possessed by various organisms. It will clear up any relation which may exist between the number of tubercle bacilli in sputum and the progress of the disease, and bring us a step nearer to solving the problem of the significance of involution and degeneration forms of bacteria."

NON-UNIFORMITY OF NUX VOMICA PREPARATIONS.—Recent assays of this important and very frequently used drug go to show that a wide degree of difference exists between the products of rival manufacturing chemists. This is a subject which deeply concerns every member of the profession, and should have early and effective attention.

Upon an examination of five different samples of commercial fluid extract of nux vomica an extractive difference of from 3 to 11 per cent. was found; while eight samples of the extract varied in alkaloidal strength between 15 and 24 per cent.

PROFITS IN FOOD-PRODUCTS.—It is frequently asserted that manufacturers of prepared foods reap enormous harvests. An instance of the truth of this statement is given in a recent issue of the *Medical Press*, which quotes the following figures in regard to the Liebig's Extract of Meat Company, of London. The annual production of extracts was not less than \$1,200,000 worth, and the shareholders received a 17.5 per cent. dividend for the year 1890. The *Press* states further that these articles of nutriment bearing the name of

Liebig have an exceptionally large consumption in Great Britain and constitute an important item in the dietetics of the sick-room and the nursery.

INSTALLED.—Prof. J. B. Hamilton, who, conjointly with Prof. Nicholas Senn, is to occupy the Chair of Surgery at Rush Medical College, Chicago, was introduced by his honored confrère, Prof. Senn, to a mixed audience of professors, practitioners, and students at the Surgical Clinic of Saturday, June 13.

Prof. Hamilton enters a large and well-organized clinic, and the lustre it already holds will scarcely suffer at the hands of the two distinguished surgeons who will hereafter have its care.

New York Academy of Medicine.

SECTION ON ORTHOPEDIC SURGERY.

Stated Meeting May 15, 1891.

SAMUEL KETCH, M.D., CHAIRMAN.

(Continued from page 860.)

WHEN SHALL WE DISCONTINUE MECHANICAL TREATMENT IN HIP-JOINT DISEASE? WITH REMARKS ON THE SYMPTOMS AND TREATMENT.

The paper of the evening, bearing the above title, was read by DR. NEWTON M. SHAFFER.

The writer called attention to the difficulty which often existed in deciding this question, and entered a strong protest against the use of an anæsthetic as an aid in reaching a conclusion. Either, it was claimed, would remove the reflex muscular protection of the joint in osteitic disease, and with Nature's protection removed, undue traumatism might be inflicted, and under the influence of this traumatism, encysted tubercular material might be broken up, and a fresh infection occur. He recognized the fact that tubercular disease must run a long course, and he had long since ceased to expect any "short cut" in the treatment of these conditions. Scientific mechanical treatment places the joint under the best local conditions for repair, and aids Nature, by climatic and other influences, in reaching the period of self-limitation, but after disintegration of the joint had once occurred, there was no apparatus that would cure hip disease, any more than a splint would cure a fractured thigh. Reference was made to the report by Dr. Lovett and the author on "The Ultimate Results of the Mechanical Treatment in Hip-joint Diseases," published in 1887. Notwithstanding the great care exercised, and the four years' limit which governed the investiga-

tion of the cases reported upon, there had been several relapses.

Attention was then called to the fact that many surgeons ignore the neuro-muscular symptoms of hip joint disease, and to the fact that the anaesthesia removes the true reflex muscular spasm; that the absence of pain was not a safe criterion; that the absence of abscess afforded no positive evidence of the cessation of the disease; and that the patient could stand a very severe concussion of the joint without pain or flinching, and yet be suffering from extensive and progressive tubercular disease; that abscesses and sinuses might exist (unconnected with the joint), and yet the patient be free from the necessity of mechanical treatment; and that sinuses might close, and abscesses disappear, with active disease present.

The author then stated that only two elements existed upon which a positive opinion could be based, viz.: 1, the gait and attitude of the patient; and 2, the character of the resistance to joint motion thus obtained. He divided the limp into three classes: 1, the limp of true disease; 2, the limp of a vulnerable joint in the convalescent stage; and 3, the limp of shortening and disease—all of which were described.

The important element, however, was the neuro-muscular protection of the articulation. He described it as a purely involuntary and instinctive effort on the part of Nature to prevent traumatism. Without this element present, we are unable, as a rule, to make a diagnosis of hip disease, and if it were not present, there would be no deformity. The mechanical treatment should be directed not only to the deformity, but to the disease, and the necessity of controlling the knee was pointed out. The author's experience led him to advise the use of the old Taylor traction splint, with the rigid pelvic band, and double perineal pad, in securing the proper modification of traumatism at the hip, and in controlling the knee; and he spoke rather disparagingly of any splint in the stage of convalescence which permitted motion at the knee. He also stated that we need not fear the effect of prolonged mechanical treatment as much as the unheeded cry of the diseased joint for proper protection.

The following conditions contraindicated the removal of the apparatus: If manual concussion produces pain or flinching; if there is considerable deformity without ankylosis; if there is a true joint limp, or if there are abscesses or sinuses connected with the joint; or if there is a true reflex muscular spasm limiting movement slightly in all directions; if there is almost perfect flexion, with the other movements considerably or markedly limited; if flexion and abduction and adduction are excellent, with rotation and extension limited; and finally, if all the movements are nearly normal except rotation inward during flexion (the limitations being due to the neuro-

muscular protection), it is not safe to discontinue mechanical protection. Rotation inward during flexion is always the last motion to recover, and this may remain for several years after all the other signs have disappeared, and in many cases it still remains after the joint had recovered; but in the latter case, its reflex character disappears.

Attention was called to the fact that after the limp had entirely disappeared, a relapse may occur. A recent case occurring at St. Luke's Hospital, was cited as an example. From this and other similar cases, the author draws the conclusion that there is a recognizable stage of hip-joint disease which antedates the limping stage.

Excising the joint was then referred to, and the conclusion reached that, in the absence of signs and symptoms by which we can exactly determine the extent of the lesion, and with the great difficulty, not to say impossibility, of a complete excision of the acetabular portion of the joint, excision was an unsatisfactory, and in many cases an unsafe operation, and that mechanical treatment, while more difficult, and requiring more special training to make it successful, promised more satisfactory results, both as to life and the usefulness of the affected member.

The conclusions were as follows:

In the first apparent stage of tubercular disease of the hip-joint, when there is no deformity present, and where we have only the neuro-muscular signs or the slight limp, or both, to guide us, as well as in the more severe forms of the disease, where tubercular disintegration of the joint had commenced, and when the muscular protection of the articulation is more pronounced, the only safe guides for discontinuing mechanical treatment are: 1, the absence of the expressive attitude and gait of tubercular osteitis of the hip-joint; and 2, an essential modification or an abolition of the neuro-muscular protection of the articulation; 3, that in all but exceptional cases, a relapse as to the deformity, or the disease, or both, is likely to occur as the result of the traumatism of locomotion, unless proper mechanical protection is maintained until the articulation is free from true reflex muscular spasm, or is ankylosed.

Dr. A. B. JUDSON shared in the general wish for more certain indications in the convalescent period. He agreed with Dr. Shaffer in thinking that the reflex or neuro-muscular signs are by far the most valuable indications of the condition of the joint. He never resorted to the use of ether in examining the joint, or to the more atrocious barbarism of striking the patient's heel till pain is produced. A patient of his had described the sensation of reflex action by saying that it resembles the general sensation felt in a swing when the descent from the highest point begins.

As but few of the superficial muscles are found by palpation to be contracted, he thought it likely that the intrinsic muscles, those beyond the reach

of palpation, are chiefly affected, and suggested that probably the muscles exhibiting these phenomena are those which, like the adductors, have their origin and insertion in the bones which enter directly into the composition of the joint. The patient or the mother is sometimes alarmed by the discovery of the rigid adductor muscle, which is thought to be a morbid growth, or an abnormal bone, till it is shown that a similar thing is produced on the well side, when an effort is made which throws the adductors of that side into tonic contraction.

He thought it well to note the variety of these reflexes. Fixation of the joint is produced by a tonic contraction, but motion, especially in the early and convalescing periods, is asserted at a varying point, when a considerable arc has been traversed, by a muscular spasm often recognized by the patient. Dr. Fayette Taylor, observing with still greater refinement, had classed "reluctance to relax," shown by the circumarticular muscles, among the reflex signs of incipient osteitis.

DR. R. H. SAYRE said that if the signs of reflex spasm continued, there was but little doubt that an unprotected joint would become deformed. An experimental removal of the apparatus seemed to be the only way of deciding about discontinuing mechanical treatment. It was true, that the late Mr. Thomas said that any one who could not tell the day and hour when the disease stopped, ought not to treat joint diseases; but his remarkable insight would appear to be quite exceptional. The existence of internal rotation and flexion he did not consider to be so significant as the author stated, for a hip which recovered with impaired motion was not necessarily a vulnerable one. It was highly important to distinguish carefully between the limitation of motion resulting from a deposit around the joint, and that due to reflex spasm. In the former, there was not likely to be any damage to the joint from the removal of protecting apparatus.

DR. WHITMAN thought the case cited in the paper, which proved fatal as a result of prolonged suppuration, should have been treated by excision, for he had seen a number of apparently hopeless cases of this kind recover after such an operation.

DR. H. W. BERG thought that reflex muscular spasm was an unconscious as well as a conservative effort of nature, and therefore he could not understand how a description could be given by Dr. Judson's patient of the sensation produced by this spasm.

DR. JUDSON replied that the reflex action in question, when spasmodic, resembles the ordinary reflexes, such as respiration and pectitation, in being recognizable by the patient.

DR. MYERS said that the case at St. Luke's Hospital, referred to, had been examined repeat-

edly for six weeks after all pain, deformity, and limp had disappeared, and the reflex muscular spasm was always detected. He had found the suggestion of Dr. Shaffer to carefully avoid outward rotation during flexion tests, a very practical and valuable one, had also noted that the same care should be used in testing adduction to avoid outward rotation, as the reflex muscular spasm at times could only be detected at the very extremes of motion. Dr. Myers said that during his observation of hip-joint disease under the tuberculin treatment at St. Luke's Hospital, he had made daily careful examinations, and had come to the conclusion that the reflex muscular spasm was the first symptom affected. In the more marked cases, the symptoms, though lasting but a few days, exactly resembled the usual exacerbation of the disease, with increase of reflex spasm, less motion, or even deformity, increase of pain, and sensitiveness, and recurrence of night cries. In less marked reactions, several times the reflex muscular spasm became more alert though there was no rise of temperature, nor appreciable increase of joint sensitiveness, or decrease of motion. He believed with the reader of the paper, that this spasm was the first and last symptom in hip-joint disease. The tubercular process he thought was self-limited, and therefore, the indication to avoid traumatic reinfection was imperative.

DR. SAMUEL LLOYD referred to a case of hip-joint disease, which he had had under observation, in which there was a recurrence after a period of nearly nine years. The proper time for the removal of apparatus could only be determined by experiment in each case. Lately, he had been endeavoring to assist the mechanical treatment of suppurative cases, by injecting a ten per cent. emulsion of iodoform in glycerine, and the results so far had been quite beneficial.

THE CHAIRMAN thought that the question of the self-limitation of tubercular disease would account very satisfactorily for the varying results obtained in the removal of apparatus. The only absolutely reliable guide was the existence of reflex muscular spasm, and although he had studied this symptom carefully for many years, he was compelled to admit that in a certain proportion of cases, it was very easily confounded with the mechanical resistance resulting from changes about the joint. The cases of so-called relapse, he was inclined to consider as a development of new foci of the disease.

He had been interested in the author's remarks about the fallaciousness of the other test, and the useless traumatism often inflicted upon joints by improper manipulation and examination.

DR. SHAFFER, in closing the discussion, said with reference to the sensations of the patient resulting from reflex spasm, that as long ago as 1876, a very intelligent gentleman had compared

this sensation to that experienced upon attempting to dodge a blow aimed at the stomach. The intrinsic muscular element would not explain the phenomena of reflex spasm, as was shown in knee joint disease, where the gastrocnemius muscle resists attempts at moving the knee joint, but allows of motion at the ankle joint. He believed that reflex spasm required for its development a peculiar specific irritation within the joint, probably of the nerves in the epiphysis. The very fact that this spasm is beyond the control of the patient's will renders it such a reliable guide in diagnosis and in deciding when to remove the apparatus. As regards the question of excision in the case referred to, he had not presented the full history of the case, and consequently had omitted to say that the father absolutely refused to give his consent to this operation. He thought all orthopedic surgeons recognized the self-limitation of tubercular disease, especially since the able paper published some years ago by Dr. Austin Flint. With regard to relapses, he felt that the traumatism of locomotion was sufficient in many cases to destroy the encysted condition of the tuberculous deposit about the joint, and hence, to produce a fresh infection with tubercular material of the vulnerable tissues in the capsule.

IRON CASTS AND COAPTATION SPLINTS.

DR. WHITMAN spoke of the advantage of employing iron splints in cases, particularly about the feet, where perfect opposition is desirable. A rough cast of the part is taken in plaster of Paris, and sent to the iron foundry, who produces an iron cast at an average cost of one dollar. On this cast, very light metal splints can be readily and accurately moulded.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

(Concluded from page 664.)

DR. S. E. MILLIKEN read a paper on "Treatment of Hydrocele by Carbolic Injection, versus the Radical Operation," in which he said that the objection to cutting operations such as Volkman's was, that although they were usually successful in relieving the hydrocele, they necessitated the use of an anæsthetic and confinement to bed for a week or more if suppuration occurred. On the other hand, the method of Levis by carbolic injection was practically painless, confinement to bed was in no sense essential, and unless an inordinate amount of carbolic acid (more than 30 minims) was used, sloughing ought never to occur. When from 5 to 25 minims of pure carbolic acid dissolved in an equal quantity of glycerine was distributed over the whole scrotal surface (2 or 3 minims in each place), nothing more than a sense of warmth was experienced by the patient. Of 54 cases thus treated by Dr. Milliken, 9 were never seen after the first injection, 5 paid one visit within the first week only, and 4 are

present under observation. All the remaining 36 could be set down as completely cured; and of these, 27 had one injection, 4 had two injections, and 5 had three injections. In no case did sloughing occur, and not one of the patients lost more than 24 hours from business.

In the case of laboring men he generally made the injection on Saturday afternoon, so that the patient could go to his work, as usual, on Monday morning. From his experience he had reached the following conclusions:

1. Carbolic injection is a safe method for the cure of hydrocele.
2. It is practically painless.
3. The patient can attend to business without more than one day's delay.
4. The disagreeable effects of an anæsthetic are avoided.

In the discussion on the paper Dr. John Murphy spoke of a case he had seen in which he believed that fatal carbolic poisoning resulted from injection of a hydrocele. He did not, however, know the quantity of carbolic acid which had been injected, and the evidence which he presented that death was due to this cause was not regarded as conclusive by those present. Dr. Wm. R. Ballou referred to the bad effects sometimes observed from the injection of iodine, and Dr. Milliken said that in using iodine he should not be so much afraid of the sloughing liable to be caused by it as of iodine poisoning. As regards the injection of carbolic acid he preferred to use 10 to 20 minims, and repeat the injection a second or even a third time, if necessary, rather than to use a large quantity a single time. In cases where the trouble returned it was always noticeable that the hydrocele was never as large as it had been originally.

Dr. Wm. R. Ballou read a paper on "Acute Prostatitis and Prostatic Abscess," in which he stated that in one thousand cases of urethritis in various stages seen by him in hospital and dispensary practice during the past five years, he had observed only three cases of prostatitis resulting in an abscess of the gland, though many that were of a milder grade. After describing the pathology, symptoms, and treatment of prostatitis he gave the notes of the three cases of abscess referred to. In one the abscess had discharged spontaneously into the rectum before the patient came under observation; in another it was tapped with a trocar through the rectum; and in the third, an incision was made from the rectum after the introduction of a Sims rectal speculum. Even if fluctuation were not distinct, Dr. Ballou advised a free and deep perineal or rectal incision in case abscess were suspected. The President thought that in the earlier stages it was preferable to make the perineal rather than the rectal incision, on account of the danger, with the latter, of the opening remaining permanently, and also of infiltration of the tissues. If, however, the case were seen later, and the abscess was evidently pointing towards the rectum he said he would perform rectal incision. He regarded the passage of a metallic instrument into the bladder with the idea of causing rupture of the abscess into the urethra as a dangerous and unjustifiable procedure.

Incidentally in his paper Dr. Ballou had referred to the local use of weak solutions of permanganate of potas-

sium in the treatment of acute urethritis; and in reply to a question from one of the Fellows he now stated that he was in the habit of prescribing at first bi-hourly injections of permanganate solution of the strength of one-eighth to one-tenth of a grain to the ounce of distilled water; two syringe-fulls being used at each injection. Internally he generally gave some alkali, and if the trouble were deep-seated, hyoscyamus in addition. After from four to eight days the permanganate was increased to one-sixth of a grain to the ounce, and sulphate or acetate of zinc (one grain to the ounce) was added to the injection. This treatment had proved extremely satisfactory, and he constantly employed it. Dr. McCollom having objected that such weak solutions of permanganate were hardly germicidal, Dr. Ballou replied that he did not believe that the gonococcus was regarded as of quite as much importance at the present time as it had been formerly.

Dr. H. W. Mitchell read a paper on "Practical Results of the Operation for Lacerated Cervix Uteri." While the operation of trachelorrhaphy, he said, was aimed primarily to restore the contour of the cervix, its most important and highest object was to insure its future usefulness in performing its normal functions. With proper attention on the part of the surgeon, healing by primary union could almost invariably be secured, and in 200 operations performed by him this was the result in all but two, where the healing took place by granulation. Of these 200 cases he had been able to follow up 21 in which subsequent confinements had taken place, all of which were personally attended by himself; and of these 21 cases, eight had had more than one subsequent confinement. All were of a severe form of laceration and in seven there was laceration of the perineum in addition. Re-laceration of the cervix during subsequent labors occurred in only two of the cases, and in both it was so very slight as not to impair the usefulness of the cervix or render a second operation necessary. Judging from these cases, he thought he could say with truth that the operation in question was proper and successful and accomplished the following results:

1. Diminish the pain and irritation following upon such a distressing lesion.
2. Relieve the sense of bearing down.
3. Cure the exhausting leucorrhœal discharge, restore the parts to their normal condition, and, above all, restore the cervix so that future pregnancies and labors will take place in a natural manner and without a relaceration calling for the repetition of the procedure.

Dr. T. J. McGillicuddy then read two short papers, one on "Objections to Ordinary Axis-traction," and the other on the "Advantages of the Anti-craniotomy Forceps over Version in Pelvic Deformities," in connection with which he exhibited the admirable axis-traction forceps and the "anti-craniotomy" forceps which he presented in the Obstetrical Section of the American Medical Association at the recent meeting in Washington. The latter, he said, was not a cephalotribe or cranioclast, but a conservative, life-saving forceps, to be used in cases of considerable pelvic deformity. With the axis-traction handles, one could determine the exact amount of resis-

tance and the proper amount of force to use, and could readily use it. He believed that when this instrument could deliver a living child, there is no other operative alternative but Cæsarean section, as he does not consider craniotomy in the living to be justifiable.

The last paper was by Dr. Reginald H. Sayre, and it was devoted to a case of "Obstinate Neuralgia following Fracture Relieved by Operation." The patient was a young man of 16, who between the ages of 8 and 13 suffered from three successive fractures of the right thigh in its upper third. After the third fracture the bones in which there had previously been straight union, united at an angle, causing a very marked curving of the thigh and between 2 and 3 inches of shortening; and there then resulted a constant neuralgia of the limb, which finally became so aggravated that he could not obtain any relief except from morphia, and so became addicted to the opium habit. The pain was the most intense at the point of greatest deformity, which was just in the line of the external cutaneous nerve. All remedies having failed in giving any permanent benefit, and several surgeons concurring in the opinion that there was a large exostosis pressing upon the vein, Dr. Sayre, on June 10, 1888, operated under antiseptic precautions. He found, to his surprise, that part of the vastus externus muscle was so twisted on itself as to turn at right angles to the long axis of the femur, but that there was no exostosis present, with the exception of a most minute point which could scarcely be considered abnormal, but which he nevertheless removed. He then passed his finger completely around the femur, stripping up the muscles for an extent of 2 or more inches; but failed to find any sharp projection, or anything else to account for the pain. Contrary to his anticipations under these circumstances, he found that the patient was completely cured by the operation of the neuralgia from which he had been suffering for six years, and which had resisted all kinds of treatment. On January 20, 1891, he received a letter from the patient, in which the latter stated that he still remained entirely free from pain, without the use of morphia or any other drug.

One of the points of interest in this case to which Dr. Sayre called attention, was the simulation of an exostosis by what was presumably a tense fibre of the fascia lata, which had become so much bound down as to press on the muscles of the thigh, and which, by girdling them, apparently caused the pain. He said he did not clearly understand how to account for the abolition of the pain. He did not consider the point of bone he removed large enough to have caused the trouble, and he did not think that when he passed his finger around the femur he tore loose any nerve fibres from the cicatrix. The explanation, he suspected, was to be found in the relief of tension given by splitting up the fascia lata, which certainly bound the muscles very tightly. The length of time that had elapsed since the operation—nearly three years—he thought was sufficient guarantee that the cure would be permanent, especially as the patient had been addicted to the opium habit, and he would undoubtedly have resumed the use of the drug if any return of pain had afforded him a pretext for so doing.

Dr. Squibb, the efficient and energetic Secretary of the Branch, to whose self-denying labors the marked success of its meetings ever since its organization has been to so large an extent due, was, of course, reflected to his old position.

During the last few months, the inhalation of vapor produced by the sublimation of calomel, according to the reports of the attending physicians, has proved a powerful auxiliary to intubation at the New York Foundling Asylum, and in some cases has apparently prevented the necessity of a resort to this procedure. Now, as soon as hoarseness is observed in a diphtheritic case in that institution, the child is placed in its crib, and a tent made over it about 3 feet in height, by means of a sheet stretched over sticks fastened to the corner posts. Placed in a wash bowl, below the feet of the child, an alcohol lamp is lighted, and over it, upon a dish, from 10 to 40 grs. of calomel are slowly vaporized. This is repeated every two to four hours, according to the urgency of the case. It is said that a Sister of Charity and nurses in the ward have been salivated by the fumes of the calomel; but, so far as known, none of the patients have been injured by it in the slightest degree. On the other hand, in some instances patients have recovered without tracheotomy or intubation, when, from the persistence of obstructive symptoms, it was highly probable that pseudo membrane had formed in the larynx. Dr. J. Lewis Smith, who is now on duty at the Foundling Asylum, states that since the vapor of calomel has been used in this way, the percentage of recoveries after intubation has been decidedly greater than was the case previous to its employment, and that when the next statistics are published from this institution, they will show very gratifying results.

P. B. F.

MISCELLANY.

GENEROUS GIFT TO TULANE UNIVERSITY.—MRS. T. G. RICHARDSON DONATES \$100,000 FOR A NEW BUILDING AT NEW ORLEANS. The medical department of Tulane University was made, June 13, the recipient of a generous donation from Mrs. Richardson, wife of that eminent physician and dean of the college, Dr. T. G. Richardson, of \$100,000. The entire donation is intended to be used in erecting a new college on Canal street, between Villere and Robertson, the site for which was bought a few days ago for \$35,000 by the Educational Board.

The faculty of the medical department of the university has selected Dr. Edmond Souchon, professor of anatomy and clinical surgery, as the representative of the faculty in the selection of the proper sort of building for the purpose intended. Dr. Souchon will leave in a few weeks for the North and East to examine various colleges to guide him in the selection of a building that will be best suited to the wants of the local institution.

DR. FORDYCE BARKER, of New York City, departed this life in the seventy-third year of his age, after a short and overpowering seizure by apoplexy. His eminence as a teacher and author in the obstetric art has made his

name a familiar one on both sides of the Atlantic. He was one of the founders of the American Gynecological Society—and the first President—of the State Woman's Hospital and of Bellevue Hospital Medical College. His greatest service to the medical profession in recent years was seen in his long tenure of the office of President of the Academy of Medicine of New York, in which position his faithful labors resulted in the building up of a fund for a fireproof and attractive home for Medicine, not only for the metropolis, but free in many respects to the whole continent—a nucleus and intellectual centre of modernized medical thought. He was a persuasive and eloquent speaker, and despite his vocal insufficiency, was as welcome an orator before large audiences in foreign countries as he was before his own fellow-citizens. He was a tower of strength to every medical cause in which he became thoroughly enlisted.

MEDICO LEGAL SOCIETY OF CHICAGO.—At the Annual Meeting held at the Grand Pacific Hotel, June 6th, Judge O. H. Horton, was unanimously elected President for the coming year; Dr. D. R. Brower, Vice-President; Dr. James Barry, Second Vice-President; Dr. Joseph Matteson, Treasurer; Dr. Archibald Church, Secretary.

Dr. Henry M. Lyman, Dr. W. Franklin Coleman, Dr. A. Holmboe and Dr. L. T. Potter were elected to active membership. ARCHIBALD CHURCH, M.D., Sec'y.
805 Pullman Building.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from June 6, 1891, to June 12, 1891.

Major Philip F. Harvey, Surgeon, leave of absence for seven days granted by order 46 C. S., Ft. Keogh, Mont., is extended fourteen days. Par. 2, S. O. 98, Dept. of Dakota, June 5, 1891.

Major Samuel M. Horton, Surgeon, leave of absence on surgeon's certificate of disability, granted in S. O. 49, March 1, 1891, from this office, is extended three months, on surgeon's certificate of disability. By direction of the Secretary of War. Par. 6, S. O. 120, A. G. O., June 4, 1891.

Lieut. Col. Charles T. Alexander, Surgeon, Attending Surgeon in New York City, is, in addition to his other duties, assigned to duty as examiner of recruits in that city. By direction of the Acting Secretary of War. Par. 21, S. O. 132, A. G. O., June 10, 1891.

Major Charles B. Byrne, Surgeon, granted leave of absence for fifteen days to take effect on being relieved from duty at Ft. McHenry, Md. With the approval of the Acting Secretary of War. Par. 14, S. O. 130, A. G. O., June 8, 1891.

First Lieut. Freeman V. Walker, Asst. Surgeon U. S. A., leave of absence for seven days granted by order 100 C. S., Ft. D. A. Russell, Wyo., is extended twenty-three days. Par. 6, S. O. 68, Dept. of the Platte, June 5, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending June 15, 1891.

Asst. Surgeon A. R. Alfred, from Naval Hospital, Norfolk, and to the "Fera."

Asst. Surgeon James Stoughton, to duty at Naval Hospital, Norfolk, Va.

Asst. Surgeon L. S. Young, to duty at Naval Station, Port Royal, S. C.

Surgeon F. H. Streets, ordered to duty on the U. S. S. "Bennington."

Medical Inspector A. A. Hochling, ordered as member Naval Medical Examining Board.

Medical Director P. S. Wailes, ordered as delegate to represent Medical Corps of the Navy at the International Congress of Hygiene and Demography, at London, Eng.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the Two Weeks Ending June 6, 1891.

Surgeon C. S. D. Fessenden, granted leave of absence for thirty days. June 4, 1891.

Surgeon Fairfax Irwin, leave of absence extended seven days. June 4, 1891.

Surgeon P. W. Mead, when relieved at Chicago, Ill., to proceed to Washington, D. C., and report to the Supervising Surgeon General for duty. May 29, 1891.

P. A. Surgeon G. M. McGirdy, granted leave of absence for five days. June 1, 1891.

Asst. Surgeon G. B. Young, leave of absence extended fifteen days on account of sickness. June 6, 1891.

CORRIGENDUM.

ORIGINAL ARTICLES.

REPORT ON AN EPIDEMIC OF CEREBRO-SPINAL MENINGITIS.

Read in the Section of the Practice of Medicine and Physiology at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY J. S. NOWLIN, M.D.,
OF SHELBYVILLE, TENN.

In presenting the subject of Cerebro-Spinal Meningitis, the first thought I offer is that our nomenclature in this as in many other diseases leads to an erroneous view of the pathology and treatment.

Our authors have almost universally written as though the inflammatory action found in the coverings of the brain and spinal column was the original lesion to be combated. It will not be necessary, for the purposes designed in this paper, to deny the fact that an inflammatory action may be found in many cases.

The error, as I conceive it to be, and to which I would direct attention, is that the inflammation, if it does exist, in a given case, is not the disease to be treated, but a sequence.

It is only necessary to call attention to the great number of deaths occurring within five days, with no exudation in these tissues evincing inflammation. It is a self-evident proposition that the cause of death is not inflammation.

Realizing the thorough knowledge of the members of this Association with the literature of this subject, I shall not burden you with quotations to prove this and other facts which I shall present. I mention however, that Dr. Alfred Stille, alluding to this question, says, "There ought to be no doubt whether epidemic cerebro-spinal meningitis should be classed with general diseases or with inflammation. It is excluded from the latter class by the total absence of any tangible external cause, as well as by its frequent fatal termination before the characteristic signs of inflammation have had time to form, or because the peculiar type of the disease prevents their development." It is clear to my mind that it is a non-inflammatory trouble and that the inflammation is only concomitant.

I remark further that the impress of the cause,

whatever it may be, is made upon the nerve centres, but before noticing directly the etiology, I submit the history of five cases which I saw in 1888.

In December, Mr. H., aged 44, was attacked. He had not been well for two or three weeks, suffering each day with pains in shoulder and neck, and in arms and back. He kept up work on his farm, and attributed his pain to rheumatism. On Saturday he came to Shelbyville, and returned home, a distance of four miles. During the day his nose bled freely. This had occurred at different times previously. He complained somewhat the same way on Sunday, at 8 p.m. had a chill, and head, neck, and eyes pained him intensely, and he suffered excessive pain in his knee joints. His throat was sore, and in less than an hour he was delirious and almost entirely deaf. Dr. A. P. Ryall was called to see him and found a bounding pulse, temperature 100°, and he could be kept in bed only by the greatest effort of three strong men. He gave him bromides with heavy mercurial purgatives, and large doses of morphia. He cupped him and poured large quantities of well-water on his head. I saw him at eleven o'clock Monday night, after he had been sick twenty-four hours. He was hardly conscious of his surroundings, his mind was entirely obscured, and he was deaf. He could see with difficulty and there was ptosis of the lid of left eye. One pupil was much more dilated than the other, and both responded to light slowly. He was continuously tossing and when still for a moment, was on the side and never on the back. There was constant desire to micturate, but the urine was voided with difficulty. Red spots appeared on his face, body and arms from the size of a pin's head to that of a five cent piece. His knuckles and wrists were especially red, and the skin in the highest state of hyperæsthesia; pressure upon the hand producing contraction of the muscles of the face. There was an herpetic eruption on the lips; the head was slightly drawn backward; he had distressing nausea and vomiting from the beginning.

We gave him six drops of veratrum viride every three hours and ten grains of quinine every hour until six in the morning.

Although he vomited frequently, we thought

he had retained most of the quinine. At that hour his symptoms were greatly improved. He was rational and could see fairly well, though one eye squinted. His stomach was quiet and he had slept some. He drank some milk and had a free and copious action from the bowels. The quinine was suspended until evening, the veratrum was not given after four in the morning. Morphia, potassium bromide and tincture of gelseminum were given through the day. He passed through the day Tuesday much better than Monday, but as night approached his ugly symptoms all returned, and notwithstanding the quinine and all other available means were pressed through the night, it was quite evident on Wednesday morning that he must die, which he did that night at nine o'clock.

On the following Friday afternoon the little daughter of Mr. H., aged 5 years, apparently in good health, and out in the yard at play, came hurriedly to her mother complaining of pain in the region of the umbilicus. She soon had shivering followed by pain in the head and neck, pulse 140; breathing rapid, with an occasional sigh; temperature 103°, delirium and sick stomach; opisthotonos marked; skin hyperæsthetic; blind in one eye from infiltration of the cornea, which was perfectly white. She had a red eruption. She was bathed in warm water, given gelseminum, quinine in large doses, and nothing left nude that promised relief. She died on the following Monday night.

On Tuesday her brother, 13 years old, had a chill, followed by pains in nape of neck, sick stomach, headache, sore throat, pain in back and a peculiar pain about the joints of the lower limbs. He was given quinine and calomel, and recovered in a few days with but little trouble. He had a similar epistaxis to that of his father, but there was no eruption. This family lives on the side of a considerable hill. The front of the house is three or four feet above the surface while the rear rests flat on the ground.

The soil on the south side and in the rear of the house was at that time continually damp. The drinking water was, for the most part, from a spring which had been dry during the summer months. Long preceding this it had been walled with wood, which at this time was in a state of decay. The washings of soil, leaves and grass, and every conceivable thing had lodged within this enclosure for years. When the stream began to run in Autumn it was very sluggish. Here, in my opinion, is the source of the sickness in this family.

On March 6th, 1889, Wm. G., aged 21, was attacked with shivering, followed by intense pain in the head, neck, back, and especially the bowels. His knee-joints were painful and he had sore throat. He had been quite unwell for several days preceding this, and his nose had bled

several times. The cold stage was followed by contraction of the muscles of the arms and hands, spells of difficult and panting breathing were frequent, his pulse and temperature were normal.

He was boisterously delirious, had sick stomach, spots on the face, herpes labialis. He was given anodynes, bromides and calomel. He also had large doses of quinine and morphia. The morphia did not affect him pleasantly. In eight hours he was given 80 grains of quinine. He also had every four hours one drop of carbolic acid and three drops of tincture of iodine in water. He had large quantities of cold water poured on his head at first, but it was soon noticed that hot water had a more desirable effect, as it quieted him for the time being. He recovered in twelve days. I may mention that after being up a few days and walking a quarter of a mile he had a relapse in which many of the first symptoms recurred. His sister had the same symptoms, but not so severe, and she also recovered.

On March 24, 1889, G. E., aged 21, living in Shelbyville, had a chill followed by a fever, pain in the head, neck, back and limbs, especially in the calves of the legs and knee-joints, hyperæsthesia of the skin, sick stomach, temperature 103°, pulse 100, tongue broad and coated. He had red spots on both hands, particularly the knuckles, and on the wrists and body. I saw him at 10 P.M. of the 24th; at that time he was only partially delirious. He had 10 grains of calomel and 40 grains of quinine during the night, with sufficient morphia to keep him quiet. On the 25th his temperature was lower and his pulse 90, pain in head more intense, patient somewhat stupid, considerable deafness, and muttering delirium.

He was given bromides, gelseminum, ergot and calomel. The tincture of iodine and carbolic acid mixture was also given. Quinine was pressed as rapidly as possible. On the afternoon of the 26th he had a convulsion, and during the night the convulsions recurred several times. His right side was paralyzed. He died on the afternoon of the 29th, having been sick five days.

These cases were of the most malignant type. Quite a number of cases more mild were treated during the months of January, February and March. They had the erratic pains which were felt in different parts of the body, headache, and pain in the nape of the neck and lower limbs. Many cases had redness of skin on hands and wrist; some had fever three or four days, others much shorter time. I could if necessary give their history in detail. There can be no doubt that the original lesion of this trouble is to be found in the nerve-centres. The rational signs point unmistakably in that direction, and the physical symptoms lead the same way. The impress of the poison, whatever it may be, is made

originally on the nervous system. I conclude from observations made not only in the years 1888-1889, but from the cases that I treated in the years from 1863 to 1867 that the real cause of this disease is malarial. The symptoms of malarial blood poison are as protean in their manifestations as the shades of the chameleon.

The three cases in the family of Mr. H. covered the extremes of these manifestations. The prodromata in the father's case was clearly indicative of nerve lesion, the same as usually produced by malaria.

The shifting and shooting pains in the body, the headache, pain in back and limbs, all point in that direction.

The epistaxis was evidently dependent on malarial toxæmia.

A bleeding nose in the early history of a fever is strong evidence of malarial origin. Herpes labialis is also often observed in the milder types of malarial trouble. If we take the three common types of malarial fever, intermittent, remittent, and pernicious, we have extremes wide enough to cover all the phenomena and peculiarities of the so-called cerebro-spinal meningitis. The young man, Mr. C., had just one week previous to his fatal attack, the most intense pains in his legs and knee-joints; the red eruptions on the knuckles of his hands. This all subsided within twenty-four hours and he was at his usual occupation for the succeeding week. I observed this periodic return of the symptoms in several cases. While the ordinary types of malaria are developed in the autumn and spring, and seldom in the winter, it is true that the pernicious cases are as apt to be developed in February and March as at any other season. I do not think the fact that cerebro-spinal meningitis has been observed in mid winter, is sufficient argument against its malarial origin. If I have succeeded in showing some facts, proving that inflammation is not, and should not, be the overshadowing symptom, and that it must not control the treatment, and further, if the cause is found in malaria, then the line of treatment is plain.

The practitioner who has confronted this dreaded disease, and who has looked through the pages of the best authorities, must feel that he goes into the battle with an uncertain guide and a trembling hand. Uncertainty as to cause, and an evident want of confidence in the remedies recommended, mark the written history of cerebro-spinal meningitis.

A disease so bold and rapid, and fatal in its results, must be met by no faltering hand. It is no new thought that malaria is the cause, but I insist that the fact has not been fully recognized, and that the treatment, both prophylactic and curative, has not been thoroughly tested because of this want of recognition.

No disease of malarial origin can be satis-

factorily treated upon general principles. It is a specific disease and requires specific treatment. Quinine is the antidote, and without no success can be expected. There are many adjuncts which must be used: calomel in large and repeated doses, venesection and veratrum, are among the best arterial and nerve sedatives, and at the same time they favor the absorption of other medicines, and the elimination of blood-poison.

The bromides, chloral, and morphia are to be used freely. The quinine should be used hypodermically in not less than 5 grain doses, and at not longer intervals than one hour; the bisulphate is the best for this purpose and can readily be dissolved in warm water. There are a few cases which cannot be controlled in every epidemic of any disease, but they all have their prodroma, and if the medicines are given in time many cases can be prevented from reaching the grave type. This is eminently true of cerebro-spinal meningitis. It is as a prophylactic that quinine is to be the greatest boon. When it is threatening to be epidemic the physician should warn his patients that the first shooting pain and the earliest uneasy aching, the slightest headache or slightest arthralgia, must be met with quinine. It is here that the inflammatory theory has done its greatest harm by withholding the hand in the fear of exciting it.

Let it be remembered that malaria is killing the patient, and not inflammation. If the patient survives the deadly touch of the blood-poison then there will be plenty of time to treat the inflammation, which is one of the sequelæ of the perverted blood vessels caused by an influence exerted through the nervous system.

REPORT OF SIX CASES OF ABDOMINAL SECTION.

By A. C. WILSON, M.D.,
OF NEWTON, CH.

Case 1.—Mrs. J. W., aged 28 years, married ten years, has had two children, elder 8 years, younger 6 years. She has had two miscarriages, one four years and the other two years ago. Her labors were always long and tedious, and her recoveries slow. Menstruated first at the age of 15 years. Always suffered great pain at these times. Since the birth of the last child, she has been a constant sufferer from severe pelvic pain, and a dull aching in the lower part of the back, rendering her able to walk but a short distance. She was treated one year for the pains with tonics and nervines, and also locally by painting the vault of the vagina with tr. iodine, and with glycerine tampons. She received no relief by

this treatment. Her suffering was so constant and extreme that the removal of the uterine appendages was proposed and gladly consented to. On October 30, 1889, assisted by Dr. H. A. Kelly, of Baltimore, Md., the tubes and ovaries were both removed. She made a rapid recovery without an unfavorable symptom. There has been no pelvic pain since the operation. She got up the fifteenth day, and in six weeks began doing her own work. She is now able to walk without discomfort, and is well in every respect.

Case 2.—Mrs. F., aged 49 years, married and has had eleven children, all still-born, except two who died soon after birth. Two years before I saw her, she received an injury in the lower part of the abdomen which caused an inflammation, and confined her to bed for several weeks. Since then she suffered constant pain in that region, and a small tumor could be indistinctly made out at that point in the abdominal cavity. She was treated for her trouble by her family physician for a long time with no benefit. An exploratory operation was performed Nov. 20, 1889, to determine the character of her trouble. The small tumor proved to be a mass of adhesions matting together the omentum and bowels. The less firm adhesions were broken up by the fingers, freeing the bowels as much as possible from constrictions. The abdominal cavity was well washed out with hot distilled water, and carefully sponged out, and the abdominal wound closed. The patient had no previous preparation, and had partaken of a hearty meal but a couple of hours before the operation. The surroundings of the patient were bad, the rooms small and filthy, but she made a good recovery from the operation. Although she still suffers some inconvenience, yet she has been much improved.

Case 3.—Mrs. J. S., aged 28 years, married seven years. Has one child 6 years of age. Has had four miscarriages, the last in February, 1890. She first menstruated at the age of 14. Since the birth of her child she has been a constant sufferer. She was first seen in March, 1890, menstruation was then occurring every two weeks. On examination I found the uterus slightly retroverted, the left ovary enlarged, prolapsed, and very painful to the touch. At that time she was weak and anæmic. Tonics including iron were prescribed. Locally she was treated with iodine and glycerine tampons. Her general constitution became better, but the ovary showed no improvement. Its removal was advised, and consented to, with the understanding that the right one should be left, unless it be found so far diseased as to be entirely useless. The operation was performed May 26, 1890. The adhesions binding the left ovary were broken up and it was removed with the tube. It was about the size of a hen's egg, containing an ab-

scence filling almost the whole ovary with pus. The right ovary, being healthy, was left. The abdomen was closed and she made a rapid recovery. Her menses came on the latter part of June. In July they failed to appear. In August she consulted me about her condition. She had morning sickness; after questioning her closely, I concluded she must be pregnant and advised her to remain quietly at home. After a couple of weeks she became quite comfortable. About the 12th of September, the next day after a ride of several miles over a rough road, in a not easy riding vehicle, I was called to see her. She had severe pain and profuse hemorrhage; in short I found her suffering from a miscarriage. The membranes came away easily, and in two week's time she was able to be up again. After a couple of months, she began to suffer a great deal of pain in the right ovary, which as yet I have not been able to relieve, and I very much fear that a second operation for the removal of the right ovary will be necessary.

Case 4.—Mrs. E. W. D., aged 30 years, has two children, the elder 7 years, the younger 2½ years. One miscarriage five years ago. Labors have always been protracted and severe, and recoveries slow. She first menstruated at the age of 16, which has always been painful. Has suffered more pain since the miscarriage five years ago. Since the birth of her last child she has menstruated every two or three weeks, constant pain in back and pelvis. Has headache nearly all the time and is very nervous. First examined her in May, 1889. Uterus slightly retroflexed, and both ovaries exceedingly painful to the touch. She was also very weak and anæmic. She was treated with tonics, and also with appropriate local applications for a year. Her general condition was improved, but there was no relief to the pain. In August, 1890, she became very much worse with the pain and was confined to her bed. The removal of the uterine appendages was advised. Consequently, September 18, the operation was performed. Both tubes and ovaries were adhered by bands of adhesions to the surrounding parts, but were easily removed. The ovaries were enlarged but contained no abscesses.

The tubes presented a granular appearance, and exuded a thin bloody pus. The patient made a good recovery, and began doing her own work and caring for a family of five members, the following January, and still continues to be well.

Case 5.—Mrs. M., aged 39 years. Has had four children, the youngest 4 years of age. The last labor very long and difficult, and was followed by puerperal fever, from which she made a slow recovery, which was never complete. Since then she has had constant pelvic pain, and also pain in the lower part of the back, and

menses appearing every two or three weeks. She never was treated for her trouble until the summer of 1890, when she became unable to work, and was confined to her bed. She received appropriate treatment, both local and constitutional, from her physician during the summer and early fall of 1890. She was first seen by me in August. Both ovaries were very painful to the touch, the left one prolapsed and lying behind the uterus. The removal of the tubes and ovaries was advised. October 10, the operation was performed. The ovaries were adherent, but the adhesions were easily separated and both tubes and ovaries were removed. The ovaries were small and sclerotic, the tubes enlarged and exuded a thick yellowish serum. The patient made a good recovery. After three weeks she went home and went to work, caring for her family, which very much retarded her complete recovery. She has continued to improve, until now she is comparatively well.

Case 6.—Miss J. R., aged 20 years. In May, 1889, she had a large cyst of right ovary removed by Dr. A. Kelly. The left ovary at that time was in perfectly normal condition and was not removed. She recovered very nicely from this operation. She was well until July, 1890, when she had an attack of dysentery; after this she complained of severe pain in the lower part of the abdomen and pelvis. She was treated with tonics for some time with little benefit. In August an examination of the pelvis and abdomen was made. Bands of adhesions could be felt in the right ovarian region. These extended from the womb and right broad ligament, and seemed to be connected with the bowels. She complained of much pain in that region, and especially when the bowels were about to move. The uterus was slightly movable, seeming to be fixed by bands of adhesions to the line of the old cicatrix. The right ovary was enlarged, painful, and slightly movable. She grew gradually worse during the latter part of the summer. In the fall she became bed-fast. The pain in the pelvis became so intense that it became necessary to give her opiates for her relief.

On December 27th, laparotomy was performed for her relief. An incision three inches in length was made at the right and close to the old cicatrix. Some difficulty was experienced in opening the peritoneal cavity, because of the adhesions of the bowel and omentum to the old cicatrix. At the right of the uterus, there was a mass of adhesions matting the viscera in this region all together. These were broken up. The stump of the old pedicle from which the cyst was removed two years ago was found, with the ligature about it, but apparently as it was left at the former operation, a year and a half before. This was left as it was. The left ovary and tube were firmly bound down and were removed with diffi-

culty. There was a great deal of hæmorrhage, but the abdominal cavity was flushed with hot distilled water and it soon ceased. The abdominal cavity was then carefully sponged out and closed without a drainage tube. I regretted afterwards that a drainage tube was not used, as there was a great deal of pain and some distension of the abdomen, which gave me a great deal of uneasiness for fear there was more oozing of blood than the peritoneum could take care of. Nevertheless she recovered slowly, and is now nearly well. She suffers no pain and walks about with no inconvenience, and is improving rapidly.

These operations were all, except Case 3, performed at their dwellings. Case 3, was done at the Youngstown City Hospital. The rooms in which the operations were done and where the patients were subsequently cared for, were all carefully cleaned, carpets and furniture removed, all wood work carefully washed with a 1 to 1000 sublimate solution. This was done in all cases except Case 2, which had no preliminary preparations whatever. All except Case 3, previous to the operations, were given saline cathartics and the bowels thoroughly emptied. They were carefully bathed, the abdomen and genitals thoroughly washed in 1 to 1000 sublimate solution. The hands of both the operator and assistant were thoroughly scrubbed with hot water and soap, and then immersed in 1 to 1000 sublimate solution for a few minutes. Nothing but hot distilled water was used in cleansing the abdominal cavity or the wound.

Silk ligatures were used for both the pedicle and the closing of the abdominal wound. These were prepared by boiling for fifteen minutes in distilled water, and then placed in 1 to 1000 sublimate solution for two hours, and preserved in alcohol. Nothing but liquid food was given for a couple of days before the operation, and no food or drink except weak tea was given for two days after the operation. The temperature of none of these cases ever rose above 100. No stitch abscesses occurred in any of the cases.

Hypodermics of morphia were given the first three days after the operation to relieve the pain, except in Cases 1 and 2.

The results obtained in these cases have been entirely satisfactory. Before the operations they were great sufferers, unable to attend to their household duties. To day they are doing their own work at home, and with the exception of cases 2 and 3 who were greatly improved, are well and happy women.

Youngstown, O., May 1st, 1891.

DR. JAMES N. MARTIN has been appointed to the chair of Obstetrics and Diseases of Women in the University of Michigan, which he has filled since the death of Dr. Dugster.

A CASE OF DOUBLE UTERUS AND VAGINA.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY M. GUHMAN, M.D.,
OF ST. LOUIS, MO.

Mrs. A., 28 years of age, married six years, well developed. First pregnancy four years after marriage—there was nothing unusual during her term of pregnancy. Dr. Langan and I delivered her on February 6, 1889, under the influence of chloroform, of a living female child. It was a breech presentation, and never entered the inferior strait, and followed by a complete inversion of the uterus, which I reported to the St. Louis Medical Society. On April 25, 1890, I was summoned again to deliver her the second time. Upon examination I found it another breech presentation. Labor progressed favorably until entering the inferior strait, and then it became firmly lodged. I sent for Dr. Langan and my son to assist me. Under the influence of chloroform and in position, I proceeded to deliver her. I introduced my fingers in the vagina, but to my surprise I could not detect any child, nor could I find the mouth of the uterus. I could feel a something through a partition, but I did not know what that partition was. I was under the impression that from the change of the position of the woman, and under the influence of chloroform, the uterus with its contents was displaced, and the mouth of the uterus was out of my reach, although thinking that such a state of affairs was impossible. I introduced my finger backwards and forwards, with always the same result. I asked Dr. Langan to make an examination. He also got his finger in the same canal, and we still were not aware that we had to deal with a double vagina and uterus. We could not detect the neck or mouth of the empty uterus No. 2, it was also drawn out of our reach. Being perplexed at finding such unusual complications which we could not account for, we agreed to send for Dr. Mooney, who resided near by. We kept our patient under the influence of chloroform. When Dr. Mooney came, he also got his fingers into the empty vagina. We concluded to make an ocular examination, which revealed a septum arising from the orifice of the urethra, and extending along the median line to the fourchette, completely separating the vagina into two canals. We introduced our hand into the vagina leading to the impregnated uterus, and delivered the woman of a living female child. After delivery the condition of the woman was such that we did not think it prudent to make any further examination. Our patient improved rapidly, and on May 11, 1890, Dr. Mooney and I made another examination, and found things as above described. In each vaginal cavity we found a well developed cervix; we introduced a uterine

sound in the left uterus to a depth of $2\frac{1}{2}$ inches. On account of some blood flowing from the uterus after our examination, and only sixteen days after delivery, we abstained from any further examination. Since I introduced a sound in the other (right) uterus, and also found its depth about $2\frac{1}{2}$ inches. From our examination and observation, it seems that both uteruses have been impregnated, the right first, and the left second; she did not menstruate during either pregnancy. It is my opinion that we have more double vaginas and uteruses than we are aware of, because it is only by accident that we find these anomalies. I have treated my patient in my office, after her marriage, for a slight flexion of one of the cervixes, with a speculum, made digital examination, and delivered her once; and I only found her condition by accident at her last confinement. All other such cases of which I have read were found by accident. For the development of anomalies of vaginas and uteruses, I would refer you to some of our text-books.

Gentlemen, I thank you for your kind attention.

REPORT OF A CASE IN WHICH THE CHILD'S ARM BECAME ENGAGED IN THE FENESTRUM OF THE OBSTETRIC FORCEPS.

Read by Title, in the Section of Obstetrics and Diseases of Women, at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY DAN MILLIKIN, M.D.,
OF HAMILTON, O.

Nearly a year ago I attended a woman who had borne four dead children after severe and complicated labors, each time under the care of a different physician. She had also borne one living child, which owed its existence to the fact that it was very small, and, probably, was prematurely born. This woman, half through her sixth pregnancy, came to me, and consented to the induction of premature labor. Thereupon she passed from my notice, changed her plans upon ill advice, and summoned me when labor at term had progressed for two or three hours.

When the cervical tissues were in proper condition, a careful examination of the case was made under an anesthetic. Finding a head of moderate size above the brim of the pelvis in left occipito-anterior position, I was sure that I could deliver it with forceps in spite of a slight asymmetry, and a shortened antero-posterior diameter of the pelvis. In this opinion I was all amiss, for it was afterwards demonstrated that the child could not be delivered in that position, and it also appeared that it could be delivered easily feet foremost. But this error of judgment is somewhat apart from my present business.

Four fingers were passed, and the forceps were

carefully guided to the sides of the child's head. They were easily locked and manifested no disposition to slip during the attempted extraction of the child. It may also be remarked that they were my pet instruments, with broad blades and strong curves, cephalic and pelvic.

No effort was made to induce pains by traction. The pains were very vigorous but separated by unusually long intervals. For this reason, and because the woman's general condition was excellent, the effort to deliver by forceps was much prolonged.

When, finally, it was determined to essay delivery by podalic version, a state of affairs was presented which, so far as I can learn, was unique in obstetric practice. The upper blade of the forceps—that one which passed to the right side of the woman's pelvis—would not come out! The lower blade was withdrawn first, and without difficulty, but still the other would not come away. Then my hand, passed into the uterus, revealed the fact that the child's right hand had passed through the fenestrum of the blade and that, in fact, the blade hung on the bend of the elbow, as a basket hangs on one's arm. The blade could not have been withdrawn without internal manipulation.

Presently, when the child had been delivered by the feet, it was seen that violence had been done to the forearm alone, and that the injury was near the elbow. No bones were broken, but the soft parts were terribly crunched. Undoubtedly, if the instrument had been long and stiff, and if it had appeared proper to compress the head very severely, the arm would have been completely chewed off.

Endeavoring to draw some warning from such a sorry job, we may note, in the first place, that the accident could only occur when a suprapelvic application of the forceps is made. To attain the odd position in which I found it, the arm must have lain for a moment with its palmar surface on the convex surface of the forceps blade as it was about to be applied to the head, then the hand must have dropped into the fenestrum, and finally, the forearm must have been flexed upon the arm by the final thrust of the blade home to its position. All of these evolutions require room, and could only occur above the brim.

In the second place, I would remark that the accident cannot possibly be diagnosed unless the head and arm are above the ordinary size. In my case the forceps were easily introduced and locked with the greatest ease; the handles were approximated as much as in the average case; there was no disposition to slip, neither when the forceps were in my hands nor in the hands of my skilled associate, Dr. Geo. C. Skinner; the child's head and the points of the forceps were repeatedly and carefully palpated through the thin abdominal and uterine tissues, and no suspicion of this

unique complication arose in our minds. I cannot believe that the most expert and experienced obstetrician could have detected the presence of the arm in the fenestrum until he attempted the withdrawal of the instruments.

For this reason I am in the humor to inquire whether the fenestrum has any reason to exist. What is it good for, anyway? It has been said in most of the systematic treatises that the fenestrum gives lightness to the forceps, but this proposition, which is at first glance very plausible, admits of question. Gave to me a solid blade that is admittedly too heavy, and I can lighten it either by cutting out a fenestrum or by grinding it thinner. If I cut out the fenestrum I weaken the blade, past question, and may need to thicken the remaining metal to restore the lost strength. Any instrument shop will furnish samples of forceps which have passed through this line of development; that is to say, they are light blades with generous fenestra and metal altogether too thick. And after all, what signifies weight in obstetric forceps? Ordinary forceps, fenestrated or non-fenestrated, need not weigh more than a pound, and it is easy to make a long pair of crushing instruments with a pound and a half of steel. Surely the brother who cannot carry a pair or two of this weight is not stout enough to be out at night, much less to use forceps.

On behalf of the fenestra it has been said, further, that they permit prominent parts of the head to engage in them—the parietal eminences, for example—in such a manner that the forceps occupy no available room, take a much better hold upon the head, and obviate the tendency to slip. To this it may be responded in the way of argument, that it is a remarkable streak of luck, and nothing but luck, when the prominences on a child's head project into the fenestra. It may be said, further, that forceps rightly chosen and rightly used for the case in hand do not occupy any available room nor, when in use, increase the diameter of the child's head measured between the blades. Fenestrated or non-fenestrated, they *make* room, moulding the head by compressing it to such a degree that were they of double thickness they would find room. And, finally, as to the slipping of the forceps, it may be said that when they show an inveterate tendency to slip, either the forceps or the operator should be changed; there is something amiss in the fit, the application or the manipulation. Fenestra will not prevent slipping when the forceps have not been placed upon the child's head, nor when they are used merely as tractors.

And it may be urged, further, that when we cut fenestra in our forceps we increase the total amount of edge surface. This is a positive disadvantage which should be atoned for by some very great advantage. Examining the head of a

child which has been the subject of a severe forceps extraction, one will find that the narrow rim of metal about the fenestrum has shown a tendency to actually cut into the tissues of the scalp. Not only the outer, convex, marginal edges make their mark, but also, in lesser degree, the inner, concave edges which bound the fenestrum. Looking at such a specimen one would incline to the opinion that the fenestrum is an evil.

But waiving the question as to whether the fenestrum has any reason to exist, I think that my mishap in the case cited gives us reason to cease operating above the brim with forceps having wide fenestra.

EXTRA-UTERINE PREGNANCY.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-second Annual Meeting of the American Medical Association, Washington, D. C., May 3, 1907.

BY DONNEL HUGHES, M.D.,
OF PHILADELPHIA.

In discussing the subject of extra-uterine pregnancy, it is advisable to begin by directing our attention to the locations at which fecundation takes place. There are three sites at which it is supposed to occur, viz.: the Fallopian tubes, the ovaries, and in the peritoneal cavity.

There are several varieties of the three species just alluded to. The tubo-ovarian is that variety in which the germ is arrested in the pavilion (the tube adhering to the ovary).

The tubo-abdominal, in which the germ is arrested in the same place as the tubo-ovarian, but instead of the tube being adherent to the ovary, it is adherent to any of the neighboring viscera.

The tubal-proper is that form in which the germ is arrested in any part of the oviduct between the pavilion and that portion of the Fallopian tube that is surrounded by the uterine walls.

The tubo-uterine, or interstitial variety, is that form of gestation in which the ovum is arrested in the part of the tube that is surrounded by the uterine walls.

Abdominal pregnancy is usually divided into primary and secondary varieties. In primary abdominal pregnancy the germ is arrested in the peritoneal cavity. In secondary abdominal pregnancy the germ is arrested in the Fallopian tube or ovary, and the cyst ruptures and allows the ovum to escape into the abdominal cavity, where it continues to live and develop.

Ovarian pregnancy is that form of gestation in which the ovum is developed in the ovary.

By far the most frequent variety is tubal pregnancy, and the most common causes of this variety are supposed to be inflammation of the mucous membrane that lines the Fallopian tubes and destroys its ciliated epithelium, thereby leaving a denuded surface for the fecundated egg to adhere

to; flexion of the tubes, which prevents the ovum from entering the uterus; hernial pouches produced by dilatation of the oviduct. When the impregnated ovum is arrested and remains for any length of time in the tube, the mucous membrane becomes hypertrophied, surrounds the egg, forms a decidua, and a placenta is developed, very similar to that which is found in normal pregnancy. When the product of conception is situated in the free part of the tube, rupture almost invariably takes place before the thirteenth week, and sometimes as early as the fourth or fifth week; when it does occur, it is either into the peritoneal cavity or between the folds of the broad ligament. When rupture takes place into the peritoneal cavity, death is almost certain within a few hours, unless the abdomen is promptly opened, the bleeding vessels secured, and all foreign substances removed. When rupture takes place into the cavity of the broad ligament, the prognosis is not so grave, as the product of conception may be disposed of in several ways, viz.: it may remain between the folds of the ligament, go to full term, and be removed when viable as a living child, or it may die and be absorbed, or it may die and suppurate, and be discharged through the vagina, the rectum, bladder or abdominal walls, or it may lie quiescent as a lithopedion, or it may become intra-peritoneal through secondary rupture.

Tubo-uterine, or interstitial pregnancy, is of rare occurrence. Rupture usually takes place before the fifth month, and when it does occur it is into the peritoneal cavity.

Ovarian pregnancy undoubtedly has existed, but is extremely rare. A few cases have been recorded. The earliest of which I can find any record is that of M. de St. Meurice in the year 1682. Marinus has reported three specimens, which are in the pathological museum of Wurzburg, which he has examined, and believed them to be impregnated ovaries. J. G. Porter reported a case of ovarian gestation in the year 1853. The autopsy showed the left ovary enlarged and containing a gravid sac, the Fallopian tube on the same side being free from adhesions. Kammerer exhibited a specimen of ovarian pregnancy to the Pathological Society of New York in the year 1865. Spiegelberg also records a case of pregnancy in the right ovary.

After carefully reviewing the literature of the subject of abdominal pregnancy, I have arrived at the conclusion that primary abdominal pregnancy has not been proved by any well authenticated cases to have existed; nor does it seem possible for a fecundated ovum to remain for a long enough time in any one position to contract an adhesion that is sufficiently firm for its development; and furthermore, if it did so, its absorption or digestion would be very likely.

I believe that most, if not all, abdominal pregnancies are secondary, fecundation usually occur-

ring in the oviduct, escaping from thence through a rupture into the abdominal cavity, and there becoming adherent to any surface with which it comes in contact.

The uterus in extra-uterine pregnancy is subject to a variety of changes, similar in many respects to those that occur when the product of conception is contained within its cavity. It always undergoes certain changes which prepare it for the reception of the ovum. Its cavity is often lined with decidua, or I might say, *always*, because in many cases it is thrown off in small shreds and is passed without being observed; in other cases it is expelled *en masse*, often leading one to suppose that an abortion is in progress; the cervix frequently contains a plug of thick mucus similar to that found in normal pregnancy. The whole organ becomes more vascular, enlarged and softened—or, in other words, prepares itself for parturition.

The impregnated germ, from the beginning to the end of its growth, is not abnormal in any way, except in its location. A portion of the fœtus may be in the uterus while the remainder is in the abdominal cavity, as in a case reported by M. Mondat,¹ in which the head of the child was in the uterus, while the trunk occupied the Fallopian tube.

Bell narrates a case² that was verified by a post-mortem, in which the fœtus was in the uterus and a portion of the placenta was within the Fallopian tube. On the other hand, the placenta may occupy the normal position and the fœtus may be contained within the tube or abdomen, as was shown by Hey,³ Putna⁴ and Hofmeister⁵ in separate autopsies where the child was found free in the abdomen, the cord extending through the tube to the interior of the uterus, where the placenta was attached.

A number of cases have been recorded in which fœtuses have been found in hernial sacs. Gouley, Geuth, Muller and others have reported such cases, the greater number of which were found in inguinal hernias.

Twin conception is another variety of extra-uterine pregnancy. It is a very uncommon coincidence to find both children in the same locality; it is generally uterine, while the other is extra-uterine. Normal pregnancy may take place while extra-uterine pregnancy already exists, and gestation advance to full term and labor take place without any unusual occurrence, provided that the pelvic outlet is not obstructed by the extra-uterine fœtus. Gordon reported a case in which a woman gave birth to five living children while carrying one that had become encysted.

The positive diagnosis of ectopic gestation in

the early stages is almost impossible in every case. There are no regular symptoms that occur during the first few weeks that are not frequently found in normal gestation. If from any cause one is led to believe, or even to suspect, that anything is unusual, a physical examination should be made. The size of the womb should be compared with the size it should be, at the supposed period of pregnancy. A careful search should be made in the neighborhood of the Fallopian tubes, fundus of the womb and ovaries. If an enlargement is discovered, so much is gained. The question then arises, to what is that tumor due? Is it a pyosalpinx, a hæmatosalpinx, a hydrosalpinx, a subperitoneal fibroma, a cystic ovary or an extra-uterine pregnancy? These questions will have to be decided by an inquiry into the previous history of the case, and by carefully comparing the symptoms of the disease which it might resemble with the symptoms of pregnancy. The size of the tumor should be compared with the size that the fetal sac should be at the supposed time of gestation. If the following symptoms are present, I think that one is justified in treating the case as extra-uterine pregnancy:

1. A previous history of sterility, or if a long period has elapsed since the birth of the last child.
2. Amenorrhœa followed in six or seven weeks by irregular hemorrhages.
3. A tumor in either Fallopian tube.
4. Slight enlargement of the uterus, with softening of the cervix.
5. The presence of decidua. The latter symptom is of great importance. A small portion of the decidua, if present, can often be obtained by passing a pair of dressing forceps into the womb, pressing them against its lining, then closing and withdrawing them. Great care and gentleness must be exercised in their introduction, and if the slightest obstruction should be encountered they must immediately be withdrawn.

If, in addition to the foregoing symptoms, there is a plug of thick mucus in the os uteri, morning sickness, enlargement of the breasts with alteration of the areola, one is justified in passing a sound cautiously into the womb for the purpose of ascertaining the presence or absence of a fœtus.

The diagnosis cannot be made with certainty until after the fourth month, when the outlines of the child can be distinguished and the movements felt. Generally, the first time we are called upon to see the case, we find the patient complaining of an agonizing pain in the lower part of the abdomen, with symptoms of shock and internal hemorrhage, which very clearly tells us that rupture has taken place. If death does not follow, peritonitis, either localized or general, is sure to develop. If the woman survives the attack, it is very likely to be repeated within a short time. When rupture takes place within the folds of the broad ligament, the symptoms are not so severe

⁵ Kusto Magazine, 1825, Vol. xv, p. 126.

or alarming; in fact, the pain in some instances has been so slight as not to have been observed by the patient herself. This form of rupture is very rarely, if ever, followed by peritonitis. If the fetal sac ruptures, the fetus dies; if it does not rupture, gestation continues until full term, unless it is interrupted by secondary rupture into the peritoneal cavity. If this accident should happen, the symptoms are the same as those that occur in primary rupture into the peritoneal cavity, except that they are much more severe, and death is certain to follow unless operated on immediately. If the fetus is carried to full term, a spurious labor will set in, and if the woman is not delivered, the child will die.

If our knowledge of the differential diagnosis of the various forms of ectopic gestation was more exact, the treatment would be comparatively simple. If we could distinguish tubal from abdominal pregnancy in the early stages, the former could be relieved and the latter allowed to progress until viable.

Many forms of treatment have been devised and practiced at different times. Among these may be mentioned hypodermic injections of various narcotics and poisons into the fetal sac, and even into the fetus itself; syphilization of the mother with the hope of destroying the child; puncturing the sac through the vaginal or abdominal walls and drawing off the liquor amnii; the passage of an electric current through the fetus with the hope of killing it. It is needless to say that these and many other devices, too numerous to mention, are hazardous to the mother, and in many instances ineffectual in the destruction of the child.

In my opinion, the only sensible and rational treatment in extra-uterine pregnancy is laparotomy. The proper plan of treatment to be pursued in all cases of extra-uterine pregnancy, except those in which the fetus is contained within the folds of the broad ligament, no matter at what period of gestation, is to open the abdomen and remove the tube that contains the fetal sac. I will go still further, and say that in a case in which a tumor has been discovered in the tube, and we are led to suspect the existence of extra-uterine pregnancy, an exploratory laparotomy should be performed, and if it is then found that the tube does not contain a fetus, the tumor, whatever it may be, can be removed. Too much emphasis cannot be laid upon the propriety of early operation, for we all know that the tube is sure to rupture, sooner or later, and, in most cases, cause the death of the woman, if an immediate operation is not performed.

When the fetus is contained within the broad ligament, it should be allowed to remain there until it becomes viable, unless secondary rupture occurs, or it should die in the meanwhile. When rupture has taken place, the abdomen should be

immediately opened, all foreign substances removed, and the bleeding vessels ligated. The peritoneal cavity should be thoroughly irrigated with warm water that has been boiled, and a glass drainage tube placed in the lower angle of the wound. When pregnancy is far advanced, and the child is either viable or dead, its removal becomes necessary. This is best accomplished by abdominal section. The incision should be made directly over the fetal sac, if possible, as by so doing the fetus, in many instances, can be removed without opening the peritoneal cavity. The child should be removed from the sac, and the cord cut as close as possible to the placenta. If the placenta be not firmly adherent, it should be removed. If the hæmorrhage from the surface of the sac which contained the placenta cannot be controlled with warm water, a sponge wet with Monsell's solution should be applied to the bleeding surface. This failing, the sac should be packed with a strip of iodoform gauze, the end of which should be brought out at the lower angle of the wound, by the side of a glass drainage tube. In from twenty-four to thirty-six hours the gauze should be removed, and the drainage tube allowed to remain until all discharges have ceased. If the placenta is firmly adherent, it should not be removed.

After thoroughly cleansing the interior of the sac and removing all loose membranes, the stitches should be so arranged that when they are tightly drawn the sac will be air-tight. If at any future time the placenta should show evidences of suppuration, the wound must be reopened, the placenta removed, and the interior of the sac thoroughly irrigated and drained.

It is needless to say that in all these operations the strictest antiseptic precautions should be observed in their minutest details.

ELECTRICITY AS A THERAPEUTICAL AGENT IN THE TREATMENT OF DYSMENORRHOEA AND PELVIC INFLAMMATIONS.

Read at the Annual Meeting of the Illinois State Medical Society, at Springfield, Ill., May 29, 1911.

BY F. J. PARKHURST, M.D.,
OF DANVERS, ILL.

EX-PRESIDENT MCKEAN COUNTY MEDICAL SOCIETY.

As a therapeutical agent, electricity has a wider range of usefulness than any other one agent known to the medical profession to-day. A great deal of good can be done with it when properly and carefully used. The ancients had a limited knowledge of its power to cure disease. Their batteries were furnished them in the form of an electrical fish, the raja torpedo, found in the Mediterranean Sea. Shocks from these torpedoes were often used in the treatment of dis-

ease. Since Galvani discovered galvanism in the year 1786, advancement has been made in the study and use of it. The past sixty years and more, especially the past twenty years, it has received much attention at the hands of the medical profession. The past seven years it has especially been used in the treatment of diseases of women. At the present time it is being lauded to the skies as a panacea by members of the profession, and equally denounced as worthless by others.

One reason for the latter opinion may be found in my own experience with the agent. A short time after commencing the practice of medicine, ten years ago, I purchased a 24-cell combined battery. Used it for two years or more as I know some physicians are using it. In time denounced it as worthless, as any physician will who uses it in a similar way. Was careless about keeping my battery in good condition, did not study the subject thoroughly, was ignorant of its methods of influencing living tissues, of the selective points for applying the electrodes, paid little attention to the strength and duration of the currents employed. Did poor work and received poor results. My battery in time got out of running order for want of proper attention, and was placed at one side in my office, where it was soon covered with dust. For two years or more made no use of it. During this time remarked that I had no use for electricity, and had but little confidence in it as a therapeutical agent, that it did not come up to the claims made for it, and have heard more than one physician make similar remarks during the past year.

In May, 1886, attended the meeting of the American Medical Association, held in St. Louis, and heard a paper read by Dr. F. H. Martin, of Chicago, on Galvanism in Gynecology. It was an excellent paper, and was well and ably discussed. After hearing this paper, came to the conclusion that I knew but very little or nothing at all about electricity, and went home resolved to become better informed on the subject. And I am pleased to-day that I can contribute something, in a practical way, of the benefits to be gained by the proper use and administration of this wonderful agent. To use it successfully, a physician must have one or more of the standard text books on electricity in his library, and study them. He should have a good battery, and keep it in good condition. He should select suitable cases for treatment, and be careful about the strength and duration of the current employed.

I have brought with me the battery and instruments used in the treatment of the cases I am about to report.

A good 24 cell battery will furnish a current of sufficient strength for all purposes, even to breaking down large uterine fibroid tumors. I have here a 50 cell Barrett chloride of silver battery.

This battery will run two hours a day for two years, equal to about two cents and a half per day, and furnish a strong current. Next, a milliampère-meter, used to accurately measure the strength of the current. The custom with some physicians, of estimating the strength of the current by the number of cells employed, should never be resorted to, as it is unreliable, and may bring about dangerous results. To produce certain results an accurate strength of current is required, and can only be measured accurately by the milliampèremeter. Next, the abdominal electrodes, which should be large enough to cover the whole abdominal surface from the umbilicus to the pubes. The first abdominal electrode I present is the Apostoli clay electrode, made very easily. Have a tin-smith cut out a piece of zinc 5 or 6 inches long and 3 or 4 wide, and solder on a binding post, get some clay, moisten and mould it to the proper consistence and size, bury the zinc in the clay and cover with thin cotton cloth; it is easily kept moist and warm. The next is the Martin abdominal membrane electrode, a very good substitute for the Apostoli clay electrode. The object in having these electrodes so large is to so diffuse the current that a large dose can be used without pain. The internal or active electrodes are composed of metal, and may be of various shapes and forms to suit the fancy of the operator. There is a difference in the polarity of the internal electrodes that is always well to bear in mind—one coagulating, hardening; the other liquefying, softening. You turn on a very strong current, and apply an electrode to the mucous membrane, which is connected with the positive pole of the battery, and the mucous membrane becomes hardened, as if cauterized with an acid. If a similar current is turned on and the electrode attached to the negative pole of the battery, and applied to the mucous membrane, the effect upon the membrane is that of solution, similar to that produced by caustic alkali. Having a correct understanding of the action of the poles, it is seen that to cure a profuse cervical leucorrhœa, to check and stop profuse uterine hemorrhage in uterine fibroids and polypoid growths of the uterus, etc., the positive intra-uterine electrode is the one to be used. Where fibroid tumors are to be broken down, a subinvolved uterus reduced in size, hardened exudates, inflammatory deposits, etc., removed, the negative pole should be employed. Before going into details, let me state that antiseptic precautions in the use of instruments and washing out the vaginal and uterine cavities, should be carried out. The first case I report is one of sterility and dysmenorrhœa.

Mrs. C., married, age 23, consulted me August, 1890, and gave the following history: She had been married four years without becoming pregnant, and was anxious to have children. Menstruation commenced at the age of 15, and was

normal, lasting about four days. About eleven months before marriage, one day while out riding and returning home, on getting out of the buggy, she stepped on the top of the wheel of the buggy and jumped to the ground. She immediately felt as if something had given way in the lower part of her bowels, was taken with a severe pain in the lower part of her back and in her limbs; was unable to walk and had to be helped into the house and to bed, where she remained for three weeks. After this accident, when menstruation came on, it was painful; that she had been slowly getting worse, and at the present time was a great sufferer at her menstrual periods. Her suffering was so great she was compelled to go to bed and take opium to relieve pain. Since marriage, in some ways she had grown worse—she had a bad leucorrhœa, menstruation now lasted seven or eight days, was profuse, leaving her weak and exhausted; almost constant backache, dragging sensations in the pelvis. Life seemed a burden, and at times was gloomy and despondent. She stated that she had consulted several different physicians, had received constitutional and local treatment with only temporary relief. An examination revealed an enlarged and engorged cervix pressing against the bladder, a profuse leucorrhœa, a retroverted uterus bordering on second degree of displacement, bound down by adhesions and immovable. My diagnosis was displacement with inflammation, plastic exudation, resulting in adhesions, brought on by the injury done when jumping from the buggy. The repeated congestions incident to married life, and also from menstruation, constantly aggravated the trouble and made it worse. Galvanism was the remedy prescribed to relieve pain, and break up the adhesions binding down the displaced uterus. The large abdominal electrode was selected for the external or positive electrode. The negative vaginal electrode, covered with wet absorbent cotton, was crowded well up into Douglas' cul-de-sac, in close proximity to the displaced portion of the uterus. These electrodes being held firmly in their places, the current was gradually turned on until it reached a strength of 100 milliampères. This treatment lasted five minutes, and the current turned off. These applications were continued every other day for the first three weeks, and three times a week the remaining six weeks of the treatment, in all twenty-nine treatments. At the end of the second week menstruation came on, with decided relief in all the symptoms. The relief from pain was such that no opium was required. Menstruation hardly lasted six days, and the amount of the flow greatly checked. The second menstruation was free from pain, and the flow stopped the fifth day. An examination revealed the uterus to be movable, so much so it could nearly be replaced to its normal position. The third menstruation was normal in every re-

spect. One month later, she became pregnant.

Case 2.—Miss N., age 21, came under my care March, 1889, and gave the following history: She began menstruating at 14 years, and has never missed a menstruation since. Her menstruations were always accompanied with pain, and for the past three years the pain had been getting worse, and "that she lived in terror of each menstruation." Her suffering was so great she had used anodyne rectal suppositories, and later morphine and chloroform. During the inter-menstrual period she had bearing-down pains over lower part of abdomen. Her appetite was poor, bowels constipated, and over-exertion was sure to bring on a severe nervous headache. She had been treated by several physicians. An examination was consented to, which revealed a retroflexed uterus; the ovaries were low, enlarged, tender and movable. The treatment used was the galvanic current. The abdominal clay electrode was attached to the positive pole, the vaginal electrode to the negative. The current employed was mild, and of longer duration from thirty M.A., and used twenty minutes every day. After each application of electricity, a small roll of iodoform gauze was crowded up against the fundus uteri, the patient directed to remove it the next day, and use a carbolyzed warm water vaginal injection every second day before coming for treatment. This treatment was continued every day, with the exception of three days, until April 12, when menstruation came on with but very little pain, the patient remaining quiet in bed. April 19 the patient returned, and the same treatment carried out. The ovaries were not so tender and higher up, nearer their normal position. The next menstrual period was free from pain, she not being obliged to remain in bed. The treatment was continued two weeks longer after this menstrual period. On examination the ovaries had regained their normal position, and the uterus found in a better position than at first. The patient had gained in flesh, had a good appetite, and could stand fatigue without bringing on the nervous headaches. Two years have passed since this patient received her last treatment, and she tells me that "her menstrual periods have been free from pain, that life seems a paradise to what it used to be, and that she is stronger and healthier than at any time since menstruating."

Case 3.—Mrs. M., married, consulted me June, 1890; has had four children; date of last confinement four years ago. Never had a tedious labor. Three years ago had typhoid fever, complicated with cellulitis confined to right side. Convalescence very slow. Menstruation did not come on for six months after getting up from the fever, and was very painful. The pain being principally in the ovarian region on the right side. She stated that for two and three days preceding menstruation, and during the first day of the flow

the pain was intense, and sometimes when the flow checked the pain would come back as bad as ever, and remain so until she flowed again. Morphine in large doses only gave relief. She took her bed sometimes a day or two preceding menstruation and remained during the entire time. Every menstrual period left her exhausted and very nervous. She also complained of frequent painful micturition and severe and annoying pruritus vulvæ often preceding and lasting a week or more after menstruation. She had received constitutional and local treatment from different physicians; said she believed there was no help for her and that she was tired of doctoring. An examination revealed the uterus symmetrically enlarged nearly twice the normal size. The uterine sound passed to the depth of three and three-quarters inches; the cervix lacerated to the left almost to cervico vaginal junction, and the mucous membrane of the vagina was somewhat thickened and pale in color. There was considerable tenderness over the right ovary and there was thickening of the broad ligament. Considering the case carefully, the character of the pain as connected with the flow, I concluded that the right ovary must be surrounded by non-elastic layers of an exudate thrown out at the time of the cellulitis. Treatment was commenced by using galvanism in strong doses. The large abdominal membrane electrode attached to the positive pole, and the vaginal electrode applied to the right of cervix uteri, and crowded well up in close proximity to the right ovary as possible. The object being to produce absorption of the exudate enveloping the ovary. Treatment was given four times a week the first three weeks, and three times a week for the last five weeks. At the end of the third week menstruation came on with decided relief in all the symptoms. There was but little pain, no trouble about the bladder and slight pruritus vulvæ. The second menstruation was normal. The fourth menstruation passed with no abnormal symptoms, and two months ago she informed me that there had been no return of pain at her menstrual periods, and I have every reason to believe the patient permanently cured.

Case 1.—Was called to see Mrs. N. November last, 1890. She had been married eleven years, had three children, one miscarriage, and one premature birth. The premature birth had occurred nine weeks previous to my seeing her, and during all this time she had been confined to the bed. I found her pale, anæmic, nervous, no appetite, very restless at night, suffering with cystitis, which was mechanical; two or three times a week she was obliged to take morphine to obtain relief from pain which was confined to lower part of abdomen. An examination revealed a large flabby subinvolted uterus crowding against the bladder, causing the cystitis. There was a great

amount of soreness over the lower part of the abdomen, but very little pressure causing pain. The patient had been unable to lie on either side. The os was large, patulous, and the sound readily passed to the depth of four and a quarter inches. She had received good nursing and been on good tonic treatment, and also received ergot and vib. three times a day. I stopped giving all medicines of any kind, and directed that the bladder be washed out once a day with one quart of warm water in which 2 gm. borac acid had been previously dissolved. Galvanism was the treatment advised and carried out. The large abdominal clay electrode was attached to the positive pole and the uterine cup electrode to the negative pole. This electrode was firmly applied to the cervix uteri. The current used was mild, 30 M. A., and used twenty minutes every day. After the first treatment the patient remarked: "I feel as if I could go off to sleep. I have faith this is going to help me." The improvement was rapid and very gratifying. After the third treatment the patient could lie on either side and the pain and soreness rapidly disappeared. In seven days the patient had a good appetite, slept well at night, became cheerful, and by the tenth day was able to sit up in a chair for the first time since becoming sick. The treatments were continued every day for four weeks, and three times a week for four weeks. Forty treatments in all. At the time of the last treatment the womb had returned to nearly its natural size. I saw the patient last week, she was looking well, had increased in weight, was able to walk and ride out.

I have selected and reported these four cases because they were cured by galvanism. No other remedy being employed in their treatment and cure by me. My list contains others permanently cured, some greatly benefited, and some not helped at all. The fact is mentioned in connection with each case that they had all received at different times first-class treatment, constitutional and local, with no relief. In the first case there was a displaced uterus bound down by inflammatory exudates, interfering with the function of the organ. In the second case repeated congestions had resulted in hypertrophy and displacement of the ovary. In the third case an unyielding exudate interfered with the function of the right ovary, and severe pain the result until the congestion was relieved by a flow of blood from the uterus. In the fourth case the uterus from some predisposing or exciting cause, or both, had failed to contract to normal size, and remained a large, soft, flabby mass, filling the pelvic cavity. The indication in each case was the removal of the products of congestion and inflammation, and the cure of pain the result. This was accomplished by the passage of electricity through the diseased tissues. I wish to state in closing, that I am not in favor of

using strong currents as I used to be. My experience and observation have led me to believe that the same electrolytic action can be obtained from a mild current for a longer time than a strong current for a short time, and with less dangerous and more pleasant effect upon the patient. There is an interesting field of observation here, and with the means we have at hand for actual measurement of the currents by the M.A., we can, before many months, arrive at definite conclusions as to the effect of the strong and mild currents in the treatment of our cases.

I am no specialist, but a general practitioner in a small town, in McLean County, and only use electricity as it is indicated in general practice. Some of the most gratifying results in my experience as a practitioner have come from an intelligent and proper use of this agent.

REPORT OF A CASE OF ABDOMINAL UTERINE TUMOR.

BY EDWARD BORCK, A.M., M.D.,
OF N. ST. LOUIS, MO.

History.—Mrs. C. N., a farmer's wife from Kansas, was sent to me by her family physician in May, 1885; she was 41 years of age, five feet 6 inches high, natural weight 96 lbs., brown hair mixed with gray, blue eyes. Had always been in good health, quiet temperament, menstruation regular, of late years some leucorrhœa. A small tumor in pelvic cavity, of about two years' growth.

Diagnosis.—Fibroid of the uterus. Ovaries not implicated.

Refused to operate, advised the patient to go home and wait until her climacteric period had passed; if by that time the tumor had not increased very much, and she would be well otherwise, then the tumor would very likely cease growing, or even atrophy, after she had passed the critical period, and need no interference. If, however, the tumor should become larger, to return, and we would see what would be best to be done.

May 15, 1891, six years later, Mrs. C. N. arrived again at my Private Surgical Home. She came determined to have the tumor removed and get well; she could not stand it any longer, something must be done for her, as the tumor had increased in size considerably. Menstruation had ceased for some time.

Examination.—Patient's weight 121 lbs., circumference over umbilicus 48 inches. Otherwise the patient was in very good condition, excellent spirits, tranquil, and not the least afraid.

Diagnosis before Operation.—Fibro-cystic tumor of the uterus, left ovary not involved, right ovary may be cystic degenerated, no adhesions except to pedicle. Taking all the circumstances into consideration, I advised the operation.

May 17, at bedtime, she took calomel gr. x, followed the next morning with a Seidlitz powder.

May 18, before retiring, a warm bath.

May 19, in the morning, a cup of milk and a slice of bread; a copious enemata of warm soap water, which cleaned the bowels thoroughly. A vaginal douche of warm water was given, and she was put to bed. At 11 o'clock morphine sulph. gr. ss, and warm water bottles to limbs and body to keep her moist, she slept. At 12 o'clock she took the chloroform with ease. I operated in my usual manner, Drs. Wm. W. Graves and Henry Summa assisting; present, Dr. L. W. Gerling, Mr. Heide-man, M.S., and Miss Henrietta A. Stoffregen, the nurse.

After opening the abdomen by an incision extending from the pubis to about 1½ inch beyond the umbilicus, a large round, solid tumor was exposed. No adhesions anywhere, the ovaries not involved, though both degenerated. On the right side of the tumor were several small bunches or protrusions from the tumor, and more soft or cystic-like, and closely surrounding the right ovary. The uterus, elongated, formed the pedicle proper, the fundus involved in the tumor.

I ligated both ovaries with a single silk ligature, separated the peritoneal covering all around, bringing into view the pedicle proper, introduced through the uterine pedicle one of my cyst elevators (double needle), tied a strong silk ligature below the needle and around the pedicle, amputated ovaries and tumor with a pair of serrated scissors, stopped all hæmorrhage thoroughly, which was very little—she lost in all not over one ounce of blood. The abdominal cavity was cleansed and flushed with the artificial serum. I then touched or amalgamated all the blood-vessels with the actual cautery, and stitched the two peritoneal folds together with interrupted fine silk ligatures, covering and inclosing the pedicles, again flushed the cavity with warm artificial serum, and closed the abdominal wound with deep-seated and superficial silk ligatures, thus obtaining a clean shut peritoneal pack. Dressed abdomen in the usual manner. The patient rallied well.

Progress of the Case.—In the evening after the operation, her temperature was one degree below normal, pulse weak but regular, respiration slow. She had been a little nauseated for a few hours, but had suffered hardly any pain, and slept at intervals.

May 20, morning. Temperature 100.5°, pulse 90, respiration 24. Some accumulation of gas in the intestine. A glycerine rectal suppository relieved her almost immediately.

Evening. Temperature normal, pulse 72, respiration 18. Otherwise in a good condition and spirits. From this time on she kept at this stage and slowly improved. Evacuation of bladder and bowels natural.

On the third day, May 22, I removed every

other deep-seated ligature; the wound was closed and perfectly dry. By the seventh day all the ligatures were out, not a drop or sign of any pus, patient was up. On the fourteenth day the patient walked out to the dining-room and took her meal with the family. For the first two days after the operation she was fed on oatmeal gruel, beef-tea, brandy, ice, according to circumstances. After that milk, meat, eggs, vegetables, etc., in addition.

The tumor weighed 20 lbs., 7 ozs. I presented it to the St. Louis Medical Society, with a short history, on the evening of the 23d of May, and made a section of the tumor in the presence of the members, and would say that to all appearance the mass was colloid, showing beautifully the uterine tissue, that is the upper part of the fundus of the uterus, from where the growth originated, with both degenerated ovaries attached.

General Remarks.—It will be observed that I took all possible aseptic precautions. Nothing but clean distilled warm and cold water was used, and the artificial serum for the abdominal cavity, instruments and ligatures. In my early operations I followed a strict antiseptic plan, carbolic acid spray, etc. In time I have learned better, and instead prefer the aseptic method, cleanliness and discipline. No opium, no medicine of any kind was used, nor was it needed in this case. This patient was an admirable patient—quiet, obedient, good spirits, with faith in her recovery. I am especially pleased that she took my advice in 1885.

This is my sixty-ninth case of ovarian or uterine tumors operated upon, exclusive of all other laparotomies for other causes. Out of my first twenty-five cases I lost four patients; out of the next twenty-five cases I lost but one patient. See report in September, 1885.

Remarks on Abdominal Surgery, with Fifty Cases. Read before the Mississippi Valley Medical Society, Evansville, Ind., September, 1885. In full in the *Medical Record*, September 26, 1885, Vol. xxviii, No. 13, whole No. 777. W. Wood & Co., Publishers, 56 and 58 Lafayette Place, New York City. Abstract from same in *JOURNAL OF THE AMER. MED. ASSOC.*, Vol. v, No. 14, October 3, 1885, 65 Randolph St., Chicago, Ill. *Med. and Surg. Reporter*, November 28, 1885, Vol. lili, No. 22, Philadelphia, Pa.

Out of last nineteen cases up to date I lost two patients; these two were operated upon at their houses. The other seventeen cases were operated upon and kept under my own immediate and constant observation at my Private Surgical Home, no death.

I would also refer the interested reader to my papers on:

Ovarian Tumors: At what Stage of the Disease is it the Proper Time to Operate? *Cincinnati Obstetric Gazette*, March, 1880, 101 Inquiries.

Ovarian Tumors (Two Lectures): Diagnosis of, and

Operation. Part I. *Cincinnati Obst. Gaz.*, September, 1883.

Ovarian Tumors, Diagnosis and Operation. Second and Revised Edition, with Six Woodcuts. Pamphlet. Cyst Elevator: Description of, and Method of Operating. Three Illustrations. *Cincinnati Obst. Gazette*, February, 1879, also *Illust. Vierteljahrsschrift der ärztlichen Polyechnick*, Bern u. Leipzig.

I cheerfully admit that I carefully select my cases I operate upon.

ON THE TREATMENT OF FIBROID TUMORS IN THE WOMB BY THE INJECTION OF ERGOT INTO THEIR SUBSTANCE.

By J. SCHENCK, M.D.,

OF ST. CARMEL, ILL.

Fibroid growths in the walls of the womb produce such serious symptoms and cause so great an amount of suffering that I believe that any method of treatment which has afforded relief or produced a cure should be placed before the profession.

It has been repeatedly demonstrated that fibroid tumors in the walls of the womb may be either checked in their growth, strangulated until local necrosis is produced, or forced out of the uterine walls by contractions produced by the free and long continued use of ergot. The methods by which the remedies have been administered are, by hypodermatic injections; by the mouth; or by suppositories per rectum or vaginam.

The inoculation of a virus to prevent or modify threatened diseases, has been practiced for about two hundred years. The most familiar examples are those against small-pox, anthrax, hydrophobia, cholera, scarlet fever, and finally, tuberculosis. Hypodermatic medication has been on trial for forty-eight years, and is to-day recognized as one of the speediest methods of carrying medicines into the system.

The profession has also had extensive experience with injections of various substances into diseased tissues and abnormal growths, as in the treatment of carbuncle, hæmorrhoids, hernia, hydrocele, goiter, nævus and vascular tumors. But I have been unable to find record of a remedy having been injected directly into the morbid growth itself in the treatment of fibroid tumors of the womb. I have administered it in this manner in several cases with satisfactory effects, and in this communication propose to present a summary of the results:

Case 1.—The first case occurred in 1880, in the person of a German woman. She was about 52 years old; otherwise in good health, had borne five children; the last, twenty years previous. On examination I found a tumor in the posterior wall of the womb, of about the size of a goose-

egg. It had tilted the womb backwards until that organ was entirely inverted; the os being high up under the pubes, while the fundus and tumor had fallen backwards and downwards, and were dangling between the thighs, a constant source of pain and annoyance. I injected one-half drachm doses of fluid extract of ergot into the substance of the tumor, once a week, for two months; at the end of this time the tumor began to suppurate and in a short time had entirely discharged. After the suppuration ceased, I replaced the womb, and retained it in position with a large sized Hodge's pessary; which the patient wore for several months, when it was removed. She is to-day a healthy old lady and suffers no inconvenience from her former trouble.

Case 2.—I was called, in December, 1886, in consultation, to visit Mrs. C. She was then 42 years old, had always lived a quiet, industrious life on a farm. Menstruation commenced at 13 years. She was married at 36; bore her first and only child in her 40th year. Menstruation had always been normal up to the pregnancy; but five months afterward metrorrhagia began, which gradually grew more profuse, although ergot was given freely by the mouth. An examination revealed a well defined intra-mural tumor in the anterior wall of the womb, encroaching on the cervix, and about the size of an ordinary orange. I advised injections of ergot into the tumor. Mr. J. D. Kingsbury, the attending physician, substantially sends me the following report:

"I injected half-drachm doses of Squibb's fluid extract of ergot each day for eighteen days, then every second or third day for ten times more, at the end of which time the metrorrhagia had ceased. She has taken ergot irregularly, by the mouth, ever since, although there have been no indications of hæmorrhage. Menstruation is regular and free but not abnormal; general health excellent.

Case 3.—In May 1888, I was called to see Mrs. T. She was then in her 42nd year; had always lived on a farm; had borne nine children; the last two years previous. Menstruation had been unusually profuse since that confinement, except during the last three months, when it had been suppressed.

On the day I was called, profuse hæmorrhage had begun, and in a short time after my arrival she had a miscarriage, of twins, at about the third month. Hæmorrhage was very free but was controlled after the womb was emptied. Shortly after her recovery from the miscarriage metrorrhagia set in, which was not controlled by the free use of ergot, by the mouth. About three months after the miscarriage, I made an examination and found a hard tumor about the size of a child's head, in the right lateral wall of the womb. By using an aspirator needle I was enabled to inject into its substance one-half

drachm doses of fluid extract of ergot, which I did once a week for nearly five months; this kept the hæmorrhage under control during this period. At the end of this time the tumor was found to be submucous, lifted up on a thick peduncle and protruding itself through the mouth of the womb. In January, 1889, five months from the time the injections were begun, I removed the tumor with an écraseur. It was so large that the wire would not reach over it, so I was compelled to take it away in three portions; hæmorrhage was not serious. The vascularity of the tumor had evidently been greatly lessened by the injections of ergot. The substance of the tumor was soft and friable and would probably soon have broken down in suppuration in a short time.

I have not observed any serious effects resulting from these injections; in a few instances a slight chill accompanied by moderate fever followed the use of the syringe; but these symptoms subsided in the course of a few hours. I have employed this method of treatment in several other cases with similar results, so far, but they are still in hand.

The most convenient instrument with which to administer the injections is the ordinary hypodermatic syringe with a long needle.

In a few instances I have used a small aspirator as a syringe. The injections are always given through the vagina. I attempt to place the ergot as near the center of the tumor as possible.

THE STRUGGLE FOR LIFE AT THE WRECK OF THE "UTOPIA."

In *The Times* of March 25, there appears from an officer on board the *Anson* a most graphic account of the *Utopia* disaster, evidently written while the terrible scene was fresh in his memory and its horror still vivid before him. While the officers of H.M.S. *Anson* were dressing for dinner the "officers' call" sounded, and all were speedily at their posts. The *Utopia* was sinking fast, and the waves washing over her were sweeping away people by dozens into the sea around. Every wave that passed over the ship lessened the numbers struggling for life. There was one man hanging by one leg to some rope aloft quite dead and nearly naked, and around were others clinging and shrieking for help. Another man had lashed himself to the sails for security, and was drowned standing up, while some of those free, and apparently in greater danger, were saved. One poor fellow, when the *Utopia* first sank, got so excited that, crying out "Oh! I can't stand this," he jumped overboard. The cold water brought him to his senses, and he was picked up and saved, but he had no recollection of what he did. Here is an instance of the effect of shock on the senses suddenly depriving the individual of the power of using them even to save his own life. We are apt sometimes to under-estimate the effect of shock in accidents less appalling, and it is only by such a circumstance as is here described that we can judge by comparison of those lesser instances of shock to the nervous system, which we are so often called on to relieve or to estimate the bearing of with regard to the future life of an individual; especially is this so in railway accidents, in which shock to the nervous system often forms the most serious part of the injury.—*The Lancet*.

PRESENT ASPECTS OF DISINFECTION.

MR. WYNTER BLYTH has lately addressed the Society of Medical officers of Health of England, regarding the latest improvements in disinfection. He finds that the basis of the scientific use of disinfectants is changing year by year as our knowledge of disease causation advances. At the beginning of the last decade, when the first results began to be revealed as to the relation of microorganisms to disease, it was the general inference that pathogenic microbes, or those concerned in the propagation of diseases of an infectious character, were almost wholly those of the sporogenic type, and that since the spores of all such organisms are possessed of a high degree of inherent vitality, no so called process of disinfection could be considered adequate and thoroughly efficient which did not have the power of destroying the vitality of the spores of the bacillus anthracis, the most resistant of them all. More recently, however, the field of vision has been clarified and it is no longer necessary to assume that there is the same degree of vitality in all specific disease-germs as exists in that of anthrax. By degrees the pathogenic microbes of very many of the specific infectious diseases have been identified and shown to be non-sporiferous, as in the case of the well-known forms of cholera, uterine fever, erysipelas, septicemia and epidemic diarrhoea; have been shown to occur as bacilli, streptococci or micrococci and to be very feebly resistant to heat and chemical agents. In this new view, therefore, it has become unnecessary to

have recourse to those powerful chemical substances, the use of which was attended by obvious practical difficulties. In a paper before the Royal Society, MR. BLYTH has already pointed out the important relations of temperature, space and time as factors in the contest with the germs of disease, showing that under appropriate conditions, even such simple means as lime-washing and aeration were competent to remove infection. BEHRING and PRUHL have recently published an account of their experiments with lime, showing its efficacy. BOER has observed that while the addition of very small quantities of lime to culture fluids favored the development of bacteria, larger quantities—as well as equivalents of potash or soda, producing an alkaline reaction, equal to what is known as 50° of normal acidity—were speedily destructive to all pathogenic microbes, in any other form than that of the spore. Hence we learn that the old-fashioned soft soaps, strongly charged with alkali, are in many cases far better germicides than the much-vaunted soaps of carbolic acid, thymol, and terebene; and that the stripping of the wall-paper, lime-washing the walls and ceiling, and the scrubbing of the wood-work with soft soap may be relied upon as generally sufficient for the disinfection of rooms or wards that require cleansing. Lime also becomes useful from its absorbent property, taking up, as it does, the sulphur compounds and other offensive gases, without itself becoming offensive; it is especially suitable in regard to the handling of disinterred bodies and for the purification of the contents of street gutters, and in nearly all cases where it will not cause the evolution of ammonia. Dr. TYKES, of London, has reported his experience of the immense value of quicklime in the removal of over two thousand bodies, and many thousand tons of very offensive soil, from a cemetery in the parish of St. Pancras to an extramural burial-place: as fast as the ground was opened, quicklime was thrown in and the stench at once ceased; the coffins were placed in larger wooden cases with a plenty of lime and, at first, lime was spread over the surface of the loads of offensive earth, after the carts were loaded, but some complaints having been made by citizens along the line of streets through which the carts were driven, he substituted a top-layer of clean earth, when no more complaints were sent in; this cemetery had

been closed for twenty years and the condition of putrefaction in the bodies were so variously and markedly offensive that without the lime the removal would have been well nigh impracticable. For the disinfection of mortuaries lime may be used, but some health officers give a preference to a fifty per cent. dilution of the Burnett fluid, which is a solution of zinc chloride, containing four per cent. of the chemical. In the disinfection of sick rooms, sulphur fumigations have had a variable reputation, and while they should not be allowed to supersede lime washing and the alkaline scrubbing, they should still be regarded as a serviceable addition to those measures. For the deodorization of excreta and stable refuse, the acid sulphates, which would fix the ammonia and at the same time not detract from the value of the fertilizer, have the preference over carbolic powders, but there are many sanitary officers who adhere to the use of solutions of corrosive sublimate, especially for the disinfecting of enteric excreta. Touching the disinfection of fomites by heat, DR. BLYTH insisted that all recent researches tended to show that time was a most important factor. Given an indefinite period of time, comparatively low temperatures have been found effective, and intermittent heatings below 212° F. may very well be employed in the purification of those articles, such as kid gloves, which are damaged by higher temperatures. In the refuges established last winter in Berlin, the use of a steam-chamber was relied upon for the disinfection of the clothing of the lodgers, while the persons of the latter were being treated to a bath; and recent German researches appear to establish the superiority of current steam over pressure steam, the steam being admitted at the upper part of the chamber and its temperature observed at its point of exit below. In regard to the carriage of infection by persons who are convalescent from infectious diseases, the discovery of Oertel must not be forgotten. He reports that he has found the bacillus of diphtheria in the throats of patients even as late as three weeks after recovery and discharge from attendance. It is possible that a like condition may obtain after scarlet fever and may explain the propagation of the disease by discharged patients notwithstanding the careful exercise of every ordinary precaution of disinfection, clothing and persons at the time of their discharge.

A NEW THEORY OF "URÆMIA."

There is no more obscure subject in pathology, than the various clinical phenomena grouped under the general head of uræmia. Of all the theories that have been advanced, it must be confessed that none of them offer a complete explanation of its varying conditions.

For years the most generally accepted doctrine, and one that contributed the name to this symptom complex, regarded it as simply due to an excess of urea in the blood; this view was then followed by that of FRERICH'S, who taught that carbonate of ammonia was the toxic substance. Further observations gave the *coup de grace* to these earlier views, and apparently demonstrated that various excrementitious substances such as xanthine, creatin, etc., were the morbid agents. Perhaps the most generally accepted view now (JACCOUD), is that any or all of these substances may be present, and in part responsible. The most striking fact against the acceptance of the view that uræmia is dependent upon the retention of normal excrementitious substances in the blood, is that animals or man suffering from fatal obstructive suppression of urine present a very different clinical picture from those affected with uræmia, the result of Bright's disease. This has given rise to the theory of REESE, which has been accepted in part by MAHOMED, that the phenomena of uræmia were dependent upon capillary hæmorrhages or serous effusion, due to changes in the blood and altered vascular pressure. It is obvious, however, that these same changes, may be, and often are, present in other diseases, that are never attended by coma and convulsions.

Perhaps the majority of clinicians incline to the view that this condition is essentially a toxæmia, though the exact nature of the offending substance has not been determined. Heretofore all researches have been conducted upon the theory that it was some substance, either changed or unchanged, that is under normal circumstances excreted by the kidneys.

Recently Dr. C. J. RADEMAKER (*Amer. Prac. and News*), May 9, 1891, has announced the discovery of a crystalline organic compound, differing from all constituents of normal urine, that he has uniformly found in albuminous urine. This substance upon ultimate organic analysis was found to have the same formula as urethane,

and to present the same general chemical reactions. As the writer points out, urethane belongs to the class of narcotic poisons, and he suggests that uræmic symptoms may be due to the presence and retention of this toxine.

Whether in this discovery we have at least cleared up the doubtful pathology of uræmic coma, remains for further observation and study. Certain it is that it suggests a new line of inquiry that *a priori* is full of promise, and one which, apparently, is capable of reconciling the wide variation in the observed symptoms in acute urinary suppression and Bright's disease.

FOURTH OF JULY SURGERY.

The usual number of Fourth of July accidents may be expected this year, especially in the large cities and among our patriotic boys from ten to sixteen years of age. In former times, the toy cannon used to figure very largely in the etiology of the injuries liable to keep the practitioners busy on the great holiday, but during recent years the giant cracker has forced its way to the front as the champion among dangerous playthings. The injuries inflicted by these crackers very commonly have their situation in the right hand, splitting open the thumb, at or near its base, and causing a compound dislocation of the proximal joint of the first metacarpal bone, tearing the latter away from the trapezium, so that the thumb and its metacarpal are connected with the hand only by the soft parts. Sometimes the explosion affects the ungual phalanx, severing it from the hand. In the report of the surgical work performed at the Boston City Hospital on the Fourth of July, of last year, there were twenty-one cases brought to the hospital as the result of explosions, the majority of which were due to the giant fire-cracker.

PURE CULTURES OF THE GONOCOCCUS.

VON SCHROTTER and WINKLER report that they have recently employed plover's egg albumen in the cultivation of the gonococcus of NEISSER. The coccus is obtained from the urethra with all possible precautions. The glands is first washed with alcohol and corrosive sublimate, then some of the infected pus is conveyed by a sterile needle to the coagulated albumen. The culture is placed in a brood oven at a tempera-

ture of 38° C. At the end of six hours a thin, whitish, transparent layer appears, that extends itself rapidly over the albumen. There is some growth at ordinary temperatures, but it is much less. Experiments with egg albumen of the common fowl were negative. *Centralblatt für Bakteriologie und Parasitenkunde*, May 23, 1891.

It is to be regretted that some more readily obtainable culture medium was not found than plover's egg. Still, even with this disadvantage, it is to be hoped that pure cultures of the gonococcus may materially advance our knowledge of this important inficiens.—Ref.

MEDICAL EDUCATIONAL INTERESTS.

The following circular has a melodious ring that clearly says: Attention, right dress, forward march. Straggling and getting out of line are strictly forbidden:

STATE BOARD OF HEALTH, KENTUCKY,

June 19, 1891.

To the Editor:—I am instructed by this Board to transmit to you for publication the following self-explanatory resolution, which was adopted at its recent meeting held in Louisville:

Resolved, That the Secretary be instructed to place upon the list of medical colleges whose diplomas are to be certified and endorsed for registration under the laws of this State only such colleges as shall, after the session of 1891-2, exact of matriculates and candidates for graduation a minimum of requirements not less than those required by the American Medical College Association.

Very respectfully,

J. N. MCCORMACK, Sec'y.

ACKNOWLEDGMENT.

For the many generous expressions of goodwill on the part of the editors of almost the entire medical press of this country, as well as from an army of friends of THE JOURNAL, we express our most hearty appreciation, and very warmest thanks.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is neither the rival nor antagonist of any part of the medical press, but in all good work for the elevation and betterment of our profession in every section of our country it may be counted upon as giving a strong support, and in utterances of no uncertain sound. Whether

we are able to realize the exalted hopes which have been so lavishly expressed or not, our friends may rest assured that we are here to do our level best to promote every laudable interest and purpose of the medical profession. In such generous, out-spoken expressions of support and tender of aid as have come to us, we recognize a determination to place this Journal away in advance of its present status, even to the making it the largest and best of its kind.

EDITORIAL NOTES AND ITEMS.

THE FRENCH-CANADIAN INVASION OF NEW ENGLAND.—There has been established a new medical journal in French, edited by E. Sirois, M.D., of Three Rivers, Mass. It is the official organ of the *Société Médico chirurgicale Canadienne-Française de la Nouvelle Angleterre*, that was founded in Worcester, Mass., in 1887. The membership now numbers over thirty, mostly from Massachusetts.

DR. ALT'S CONNECTION WITH THE ST. LOUIS MIRACLE (!):—The so-called "miraculous" case of Sister Mary Philomena at St. Louis not long since, and with which it has been reported that Dr. Adolph Alt, editor of the *Journal of Ophthalmology*, was in some way professionally connected, is disposed of by Dr. Alt in the current issue of the journal over which he presides.

Dr. Alt denies in unequivocal terms having any connection with, or knowledge of, any miracle. Dr. Alt said he was called upon one occasion—previous to the reported miracle—and found a congested upper eyelid in the patient, with a history of bleeding from the part—presumed hæmophila. He then adds: "This is all I know of the miracle case. I saw the Sister only that once. I did not do anything for her. I had nothing to do with the subsequent alleged miracle, and could, therefore, not vouch for it, even if I believed it."

THE BRITISH MEDICAL ASSOCIATION.—The fifty ninth annual meeting will be held at Bournemouth on Tuesday, Wednesday, Thursday and Friday, July 28, 29, 30, and 31, under the presidency of Willoughby Francis Wade, B.A., M.B., F.R.C.P., J.P. The address in Medicine will be delivered by T. Lander Brunton, M.D., F.R.S.;

the address in Surgery by John Chiene, M.D., F.R.C.S., Ed.; the address in Public Medicine, by Edward Cox Seaton, M.D.

The scientific work is divided into nine sections, viz., Medicine, Surgery, Obstetric Medicine and Gynecology, Public Medicine, Psychology, Pathology, Ophthalmology, Diseases of Children and Therapeutics, and already an average of eight papers in each section has been announced.

A brief description of the place of meeting will be of interest, especially to those who have lately enjoyed the beauties of our National Capitol at the meeting of the American Association.

Bournemouth is a happily situated watering-place on the southern English coast. A valley of about two miles or more in extent, beautifully cultivated, and through which winds a small stream, gives a place for pretty homes, and one of those quiet English towns so famous in the literature of the country—the literature of the English-speaking world.

A broad beach of white sand, wooded hills, the sparkling sea; together with the calm, joyful surroundings made by the hand of man, and the smile of the summer's sun, should all conduce to the success of the occasion, and we doubt not that such will be the case. Various points of interest and pleasure are within easy distance, and excursions have been arranged, giving, therefore, a decidedly sociable trend and interest, other than purely scientific, to the gathering.

MEDICINE VS. SURGERY.—Viewing the height to which the science and art of Medicine and Surgery is advancing, and the struggle of both branches to attain the higher meed of praise; looking over the whole field of progress and possibility through the glasses of "A Quinquennial Retrospect," Dr. Grigg, in an inaugural address before the British Gynecological Society, said: "The greatest operative skill that ever man possessed must pale before the discovery of a drug or of an agent which can arrest or destroy the effects of pathological changes. We are on the threshold of great discoveries. Another century will not pass without increasing our therapeutical resources at the expense of the surgeon's art."

ARTIFICIAL INFANT FOODS.—Dr. C. W. Earle, of Chicago, maintains strongly against the prepared infant foods—the commercial foods so much

advertised and used. Above all else, of course, he contends that the mother's milk is the food *par excellence* for the infant's stomach and bowels. If this is not of sufficient quantity, then a prepared food may be resorted to only to fill out the deficiency in quantity. If it becomes *imperative*, then a prepared food may be wholly used. Condensed milk, properly diluted with rice water or toast-water, and sterilized, has been used under his care with the best results. He strongly advises the sterilization of all infant artificial food, and the use of the improved "feeders." The old-time nursing bottle he denounces as a thing of evil.

A VIABLE CHILD AT SIX AND ONE-HALF MONTHS.—Dr. Herman L. Collyer reports *Arch. of Gynecology*, June, 1891, a child born before six and one half months of uterine life had been reached. The dates were well distinguished; that is, the time of conception was well ascertained, and the progress of the case from such time was carefully watched. At birth the child weighed two pounds and two ounces. The finger-nails were just beginning to show, while the toe-nails had not yet shown development. The cranial bones were soft, the sutures overlapped, while the frontal suture was open. The child immediately after birth was carefully wrapped and nursed, and continued to live.

Viable children at this age are very uncommon, and even when one is reported, the chances of an error in calculation render it difficult for positive statements.

THE COMPOSITION AND TRUE NATURE OF TUBERCULIN.—It is said that Prof. Koch, having returned to active laboratory work at Berlin, will soon announce full particulars regarding the preparation and essential characters of tuberculin.

THE ST. LOUIS SURGICAL SOCIETY.—This is the title of a new organization of the working members of the profession in St. Louis—those working members to whom surgery has made an especial appeal, and who feel called upon to reply with their choicest gifts and the day and night toil of their minds and hands.

THE AMERICAN SOCIETY OF MICROSCOPISTS.—This Society will meet at Washington, D. C., August 11. In 1878 the first organization was effected, beginning with about seventy-five mem-

bers. Since then it has grown until now its membership list shows upwards of four hundred names. Yet the number is not what it should be, and a plea has been presented by the Secretary for more interest—for a larger list of members, and an increased activity on the part of those already belonging to the body.

The indispensable value of the microscope to medicine, together with the fascination of the study, should invite many physicians to show their zeal along this line by rendering such assistance as is within their power to this National organization.

ADVANCED SURGERY.—M. Figueira, M.D., of New York City, believes an operation for foreign bodies at or below the bifurcation of the trachea can be made from the posterior thoracic region—between the posterior scapular margin and the vertebra. He is convinced that vital structures could here be avoided and the roots of the lungs reached. The sad case of the Rev. Dr. Bothwell, regarding which the country is aware, has prompted him to undertake experiments, the results of which he promises soon to make known.

DOMESTIC CORRESPONDENCE.

Tuberculin.

To the Editor:—I note the report of Dr. Joseph Jones, of New Orleans, La., upon the analysis and examination made by him of Professor Koch's lymph, now called tuberculin, which appeared in your issue of May 30.

Without in the least desiring to appear as the champion for the lymph, the extraordinary statements made by Dr. Jones in this report, led me to reply to his claims of having found living tubercle bacilli, or at least such as resembled and behaved similar to the bacilli of tuberculosis.

Many similar analyses have been made and published before and since Dr. Jones began his investigations, but strange to say in none of the numerous experiments made in the physiological and bacteriological laboratories of Europe and other countries have ever any living germs been found to be present in the fluid.

Dr. Jones says, that upon the dilution of the lymph with boiled distilled water and preserved in chemically clean test tubes, the fluid became turbid, and that microscopic examination showed the turbidity to have been due to the multiplication of organisms presenting the physical and chemical properties similar to those of the bacillus of tuberculosis.

He does not state the degree of dilution and the length of time it required for the turbidity to occur. Boiled distilled water may and may not be sterilized

water, and chemically clean test tubes, may not be sterilized and may not be clean in a bacteriological sense. Neither does he show that the turbidity could not also have been due to the development and growth of the germs.

The care and facilities for correct and unassailable investigations in these matters are such, that a lack or the slightest deficiency in either direction would make any conclusions certainly very doubtful, if not valueless. I have myself kept such a 10 per cent. solution for over five months, and without all the precautions necessary to prevent error, and the fluid has not become turbid, neither can the most careful examination show the presence of bacilli, dead or alive. I have kept half, 1 and 5 per cent. solutions without especial precautions for a number of weeks and they were perfectly clear at the end of such time.

Now as to the results of culture as obtained by Dr. Jones they are certainly remarkable, and it would be of the greatest interest if the report contained exact data of the steps and modes of his procedures, the way in which the culture media were prepared and kept after inoculations, and the time and the precautions under which he made his final examinations.

Dr. Jones being until now a stranger in the field of experimental bacteriology, it would not be unreasonable to ask of him evidence for the remarkable statements which he makes, the more so inasmuch as men who have at their command the perfect equipments of bacteriological laboratories of Europe and other countries, and who have earned a world-wide reputation in this special field of scientific labor, and who have made similar investigations with Koch's lymph, have never found any tubercle bacilli capable of growth and multiplication, in that fluid.

That the lymph contains dead or inert bacilli has been well known since the first introduction, and can be found especially in the sediment of occasional specimens, but heretofore, so far as I know, all culture and inoculation experiments have failed, and from the mode of preparation we must expect them to fail, if no germs are admitted by error or oversight from without. These dead bacilli, are, however, not found so plentifully even in the sediment from a bottle of tuberculin as one might suppose from Dr. Jones' report; only here and there we find a bacillus in the field, and more often none at all. Their presence and inertness were known to Professor Koch and his associates, from the beginning has been referred to in the medical literature again and again, and the mode of preparation with prolonged exposure to intense heat of the fluid, and its preservation in glycerine after filtration through porcelain, is a sufficient guarantee that we have nothing to fear from them. Moreover, every vial before being sent out of the laboratory is especially tested and examined.

Dr. Jones should or could have known of the presence of inert bacilli, and of the negative experiments of other experiments before he undertook the examination of the vial submitted to him, and certainly before he published his report.

This question, which in Europe finds now no further at-

tention, having come up in America, it would certainly be interesting if Dr. Jones would repeat his experiments, and, if from the same sample some well known bacteriologist, as for instance Professor Sternberg, or Ernst, could be induced to make control experiments, for such matters require to be definitely settled in the interest of science as well as that of the profession and patients.

It is certainly not intended that living tubercle bacilli should be contained in the tuberculin, and contrary to Dr. Jones' conclusions its action does not depend upon their presence, and this Dr. Jones must also have known when he made his report. To me his concluding remarks are entirely unnecessary or hardly in good faith when he refers to the remedy as a secret medicine, Dr. Koch having given the temporary secret of its source and composition to the world before Dr. Jones came into possession of his vial. In the meanwhile those who use the remedy, if influenced by Dr. Jones' report, can make assurance doubly sure, by subjecting every solution for clinical use to prolonged boiling, which in no wise interferes with its action, and which I, and as far as I know, others who have applied it, have always done.

The addition of $\frac{1}{2}$ per cent. of carbolic acid can also be increased to any desired strength, as for instance, the 10 per cent. solution of tuberculin which we make from the original vial can contain 5 per cent., or 50 per cent. of carbolic acid may be added to the lymph, and its 1 per cent. solution would then still only contain $\frac{1}{2}$ per cent. of carbolic acid as originally intended.

I here also found that tuberculin solution containing as much as 1 or 2 per cent. of carbolic acid crystals are not specially painful or objectionable for hypodermic use. There can be no doubt, that the preparation of the tuberculin is in reliable hands, and that any findings justifying even the remotest suspicion as to the presence of active tubercle bacilli or other microorganisms would promptly lead to a revision of, and increased precautionary measures in its preparation, for indeed, it cannot be a matter of great difficulty to sterilize the remedy, and control experiments are daily being made in the laboratory of its production.

Respectfully yours,

KARL VON RUCK, M.D.

Winyah Sanitarium, Asheville, N. C., June 3, 1891.

Vote of the Missouri State Medical Association upon the "Three Years Course."

To the Editor:—As a part of the medical history of the West, the attitude of Missouri towards the great question of educational reform now agitated all over the country, must attract general interest. In THE JOURNAL, April 11, 1891, an account was given of the history of the Three Years' obligatory Medical Course Bill in the Missouri Legislature; Indorsed in a memorial by 1,700 doctors from all over the State, and by a large majority of the fourteen medical colleges chartered by the State, the Bill was unanimously recommended for passage by the committees of both House and Senate. The House passed the Bill by a vote of 85 to 22; it came before the

Senate during the last hours of the session, and was defeated by a vote of 5 majority—a number of the Senators had already gone home, including friends of the Bill. A more flagrant violation of the principles of democracy and defiance of the will of the people, can hardly be instanced. At the annual meeting, May 20, of the Missouri State Medical Association, the following resolution was introduced:

That the Association urge upon the State Board of Health that it define the statutory phrase "college in good standing" as affecting the value of diplomas shown by applicants for license to practice medicine, to apply only to such colleges as require attendance upon three annual courses of lectures and clinics, of six months each, and that a copy of this resolution be sent to the Governor of the State, and to the State Board of Health.

This emphatic resolution was adopted by a vote almost unanimous, after all had time to take part in the discussion. Thus the representatives of the profession in Missouri have placed the State absolutely on record as desirous of the reform, and at the same time, they have put the stamp of their condemnation upon those who, through political juggling, have for the moment defrauded the State of necessary legislation, and betrayed the cause of science and of the people.

As proof of the complete unanimity of opinion in the State upon this subject, the homeopaths, in convention at Kansas City, April 22, passed a resolution identical in spirit with the one above given. The following is taken from the organ of the eclectics, the *American Medical Journal*, St. Louis, April, 1891:

"In the senate it (the Three Years Bill) was defeated. This strange procedure may be understood in this way: If the Bill had passed the Senate, the Governor would have to sign or veto it. To veto would have incurred the displeasure of the great majority of physicians throughout the State, as well as that of the Senate. It would not have been the policy under the existing crisis. To sign the Bill would have offended some special friends."

That the influence of politics upon science is notoriously harmful, the events briefly summed up in this communication afford one more glaring illustration. Respectfully,

CHARLES A. TOPP, M.D.

Chairman Com. Scientific Communications, Missouri State Medical Association.

St. Louis, June 6, 1891.

FOREIGN CORRESPONDENCE.

LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

In several instances of late pneumonia has been most successfully treated by large doses of digitalis. By some medical men the expectant method of treating pneumonia is thought to be not only irrational, but even dangerous, and that the assumption that there is a definite cycle of progress in pneumonia is not warranted, and from experience obtained at the leading London hospitals, the disease may be jugulated or cut short by an energetic, rational mode of treatment, especially if the method is inaugurated at the onset of the disease, and

that, if by the claim is supported that the treatment of pneumonia with large doses of digitalis promises better results than those obtainable by any other mode of procedure.

Dr. Steele has drawn attention to some useful precautions in the extraction of broken needles. He says that it is most unpleasant, after cutting and probing with the fingers, and forearms, to be obliged to cut a patient that further attempts are useless, and that the fragment is still there. The plan he adopts is very simple, and easy and reliable. In the first example which he gives, the patient, a young lady, had been unable to rest her left foot on the floor in walking for some weeks, as she had broken a needle in her left heel, and the slightest touch gave great pain. The point of entrance was visible in the middle line, over the os calcis. The end of the needle could be recognized through the skin, but the slightest pressure caused it to recede. Dr. Steele applied two thick felt corn-plasters, one on the other, with the puncture occupying the central hole, and ordered the patient to walk freely and bear well upon the heel. This she did with perfect ease, and after ten days the needle presented and was easily withdrawn. Dr. Steele points out that the ball of the thumb and the wrist are not infrequently punctured, and if the fragment enters obliquely, and lies close to arteries or nerves, and cannot be forced into prominence, attempts at extraction are undesirable, whereas by adopting this simple method, and producing pressure with an elastic ligature or light steel spring like a small truss, the fragment will work out, and not give pain from any knocks while under the skin.

Sir Arthur Mitchell and Dr. Buchanan have discussed the influenza epidemic of the first three months of last year in a paper on "Influenza and Weather of London," published in the latest issue of the journal of the Scottish Meteorological Society. In the forty-five years from 1815 down to the end of March, 1890, the total number of deaths attributed to influenza registered in London was 129, or an average of 10.12 per annum. It will surprise many that, strange as the epidemic was thought to be during its advance from the East towards the close of 1889, deaths from this particular malady have been registered in London every year from 1815. There were in all five epidemic outbursts, viz.: December, 1847, to April, 1848, 1,091 deaths; March to May, 1851, 288 deaths; January to March, 1857, 130 deaths; November, 1857, to January, 1858, 123 deaths; and January to March, 1869, 515 deaths. These visitations, therefore, cost 2,087 lives, leaving 2,065 to be distributed over the non-epidemic forty years. Latterly there was a great diminution of the yearly totals, the six years to the close of 1880 having only twenty-five deaths between them. The distribution of the deaths over the fifty-two weeks of the year shows that the numbers registered in the three months, December to February, were enormously in excess of those registered from May to September, so that there was a strongly-marked winter maximum, and a summer minimum. A secondary maximum was also shown towards the end of March and beginning of April. The authors enter into details connected with the five epidemics, and decide that, although the visits occur generally in the

winter months, they are not related to very cold weather, but to periods of high temperature which manifests itself both before and during the visitation. Information has also been collected bearing upon eighteen other influenza epidemics between the years 1510 to 1637, but as to most of them, owing to the imperfect nature of the records, there was little if any real value that could be ascertained. They were made up of winter, spring and summer epidemics, the weather being of a very varied description; the 1762 visitation being accompanied by unseasonable and intolerable warmth, and the summer epidemic of 1767 being preceded by uncommonly cold weather. So far as can be gathered from the records from 1658 to 1890, the complications and sequels which result from winter attacks appear to be chiefly diseases of the respiratory organs and circulatory systems, the nerve centres having a tendency to be more affected by the spring than by the winter epidemics, while summer influenza induces a prevalence of diarrhoea, coincidently and subsequently. The epidemic of 1831 was the only summer one of the present century.

A German medical man has noticed, in a great number of cases, that tuberculous granulations completely disappear if the wounds be thoroughly covered with fat. This has led him to the thought that in many infectious diseases, the mechanism of the taking up of microbes by the white blood corpuscles or leucocytes sufficed to explain the curative influence of various agents. Restoration of cells and avoidance of injury to the tissue is especially to be regarded, he says. If now the leucocytes can be increased in the tissue itself, without the latter being affected, certainly the diseased condition will be altered for the better. The remedy must be taken up by the leucocytes in the same manner as bacteria are taken up. As regards fat, this process is thought to be best obtained by the free use of olive oil.

A special Indian Committee has been formed in connection with the International Congress of Hygiene, to be held in London, under the presidency of the Prince of Wales. Sir Douglas Galton is chairman of the organizing committee. Dr. Clave Shaw has contributed a highly interesting memoir to the new volume of the St. Bartholomew's Hospital Reports under the title "Fractured Ribs in the Insane." In his endeavor to throw some light on the pathology of broken ribs in the insane, he has made experiments as to the weight required to cause fracture of the rib. He has come to the conclusion that a considerable difference exists not only in the weight of the ribs on the two sides of the body, but also in the average breaking weight. He has frequently found that a tight rib will bear the heavier weight, and also that there is no proportion between the weight of the rib and the number of pounds that it is capable of sustaining, therefore it is probable that physical conditions of structure have more to do with the strain-resisting power than chemical change. Dr. Shaw has also noted that patients suffering from advanced phthisis, frequently have ribs that support a strain much above the average, whilst persons suffering from disease of the heart or blood-vessels invariably bear less strain than others. When a fracture is caused by a blow, it is de-

pendent not so much on the weight of the rib and its power of bearing strain as upon other conditions. Dr. Shaw does not agree with the idea that the ribs of the insane are generally more brittle than those of the sane. Where extreme brittleness does exist it is almost confined to those affected with degeneration of the circulatory system.

Mr. George Holt has sent the council of University College, Liverpool, £10,000 for the endowment of a chair of physiology. It has been decided to request Mr. Holt to permit his name to be permanently attached to the professorship. The present holder of the chair has sent a letter resigning the position in consequence of increasing work of other kinds.

Dr. Alexander Fraser's new "Guide to Operation of the Brain," contains photographs of the human brain which have been made upon the following plan: After suitable hardening and preparation the head was photographed, and then dissected layer by layer, each layer being photographed in its turn. Further, the art of composite photography has been utilized, so that one is enabled to gaze through the shadow of the superficial structures upon those which are deeper. Thus at a glance the clearest notion of the position of the convolution of the island of Reil, of the cornua of the lateral ventricles of the corpus stratum, can be obtained, each in their respective relation to the surface.

G. O. M.

BOOK REVIEWS.

PRACTICAL POINTS IN THE MANAGEMENT OF THE DISEASES OF CHILDREN. By I. N. LOVE, M.D. The Physician's Leisure Hour Series. Detroit: Geo. S. Davis.

The author states the *raison d'être* of this little volume is to group together a number of practical points pertaining to various disturbances of childhood which have come under the direct observation of the writer. It is not advanced with the idea of completeness, nor to take the place of the various larger works; it is rather to supplement them, as it contains many excellent and practical suggestions that will be looked for in vain in more ambitious treatises. The work bears abundant evidence that it was written by one enthusiastic in his subject, and almost wholly from the standpoint of personal observation. Whatever has been gleaned from other writers has been sublimed in the crucible of experience, and received the stamp of the writer's originality and experience.

In a book bristling with good points, it would be perhaps invidious to single out some for special mention, but we cannot let the occasion pass without referring to the close of the chapter on artificial feeding, in which the writer says: "We must always bear in mind that every baby, like

every other individual, is a law unto itself, and there can be no stereotyped rule for the artificial feeding of infants." Again, under the general chapter, we find the following: "We should make it the object of our lives to teach the parents of the children under our care that an indefinite amount of prevention is better than an indefinite amount of cure. Every day's sickness checks the proper development of the child, aiding in the direction of a delicate organization rather than a strong one."

The work is excellently arranged, easy of reference, and has a good index.

DE LA TUBERCULOSE MAMMAIRE. Par le DR. ADRIEN W. ROUX. Genève: Henri Stapel-mohr.

This small monograph on tuberculosis mammae is an example of useful compilation. While it adds nothing especially new, yet it arranges and classifies our knowledge of a particular subject in such manner that it is readily accessible.

The work is divided into two portions. The first deals with the history, etiology, pathological anatomy, symptomatology, diagnosis, prognosis and treatment of the affection. The second part consists of an abstract of thirty-one previously published cases, to which the writer has added three observed by himself. The work is illustrated by three excellent plates, one of which is colored.

THE INTERNATIONAL MEDICAL ANNUAL AND PRACTITIONER'S INDEX. A WORK OF REFERENCE FOR MEDICAL PRACTITIONERS. Ninth year. 1891. Forty eminent contributors.

The present volume, from the well known house of E. B. Treat, New York, 5 Cooper Union, and Chicago, 199 Clark street, fully maintains the hitherto well earned reputation of this series of annuals. The present work contains about 600 pages octavo, and is afforded at the remarkably low price of \$2.75.

Part first contains a review of the therapeutic progress for the year 1890, by Percy Wild, M.D. Antipyretics, hypnotics and analgesics are well considered, the first fifty pages of the work being devoted to the discussion of new remedies.

The body of the work is given to the consideration of diseases, the subjects being arranged, alphabetically, and the recent and most accepted methods of treatment are briefly given.

This feature of the work renders it especially valuable to the busy practitioner as a book of ready reference, and at a small cost adding much valuable information on a great variety of subjects for the use of those whose means and libraries are as yet limited.

Among the subjects which are considered are monographs, and which will repay perusal, are "The Motor Centres of the Brain," by W. H.

Elam: "The Diagnosis of Functional and Organic Diseases of the Heart," by Drs. Leaming and Jackson, of New York; "The Sputa as a Means of Diagnosis," by Dr. F. J. Wethered; "The Hand as a Diagnostic Feature in Diseases of the Nervous System," etc.

Chapters upon Sanitary Science, Climatology and Hygiene, Alcoholic Inebriety, Pharmacy and New Inventions conclude the work. As a *résumé* of medical progress for the year it will be found valuable, and will many times repay its cost.

MATERIA MEDICA AND THERAPEUTICS. By JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine, and Clinical Professor of Diseases of the Skin in the Medico-Chirurgical College of Philadelphia; etc. Volume II. Phila. and London: F. A. Davis, 1891. Price, \$3.50.

This is the second and final volume of a work which has engaged the attention of the author for some time. We have noted quite every page of the volume, and feel pleased and benefited for so doing. As in the first edition of all other efforts, so here there is a demand for the critic's pen. And yet there is not, we confess, that shortcoming we had rather prepared ourselves for. Rapid authorship does not usually conduce to thoroughness, and that weighing of evidence which a medical text-book should have; and for this reason, if no other, we were inclined to be unsparing in search and statement.

To the writer—who has turned almost daily to Bartholow's *Materia Medica*—the most serious fault in the make-up of Dr. Shoemaker's work, is the absence of an index of diseases.

The amount of space given to prescriptions, and to a description—however brief—of many drugs which were long since obsolete, cannot have our commendation. To the early student, however, we can see where both of these points may be of value.

The alphabetical arrangement of drugs we like. The clear description of the recent remedies makes it at once quite indispensable to the wide-awake and progressive physician.

SEXUAL NEURASTHENIA. By GEORGE M. BEARD, A.M., M.D., formerly Lecturer on Nervous Diseases in the University of the City of New York, etc. Edited by A. D. ROCKWELL, A.M., M.D., Professor of Electro-Therapeutics in the New York Post-Graduate Medical School and Hospital, etc. Third edition. New York: E. B. Treat, 1891. Price, \$2.75.

The third edition of a work which has become standard in its line. The subject is one of much importance, though one of difficulty and delicacy. Notwithstanding this, however—the difficulty and

delicacy—Drs. Beard and Rockwell have given the profession a work to which it may refer with a confidence of the latest and most scientific light upon a topic which quackery has forced into undue public prominence.

MEDICAL SYMBOLISM. By THOMAS S. SOZINSKY, M.D., Ph.D., Author of "The Culture of Beauty," etc. Illustrated. Philadelphia and London, F. A. Davis, 1891. Price, \$1.

For the student in this line—for he who has time for the less practical side of medicine—interest and profit will follow the perusal of the pages of this little volume. Without attempting to advise the hurried man of to-day, yet we may say that to the average mind a healthfulness of thought obtains from comparisons, even remote though they be; and a comparison between the old—the very old—and the new—between mythology and fact—in the realms of medicine, is afforded in the study before us.

MISCELLANY.

THE PHILADELPHIA POLYCLINIC and College for Graduates in Medicine continues to reach out for additional facilities in the way of study and research for its large class of students. It has just elected five new lecturers. Dr. H. R. Wharton, who is Surgeon to the Children's Hospital and to the Presbyterian Hospital, has been elected Lecturer on Surgical Diseases of Children, a part of his course being Tracheotomy and Intubation.

Dr. C. P. Noble, surgeon in charge of the Kensington Hospital for Women, has been elected Lecturer on Gynecology.

Dr. James K. Young, surgeon to the Orthopaedic Department of the University Hospital, has been elected Lecturer on Orthopaedic Surgery.

Dr. G. Betton Massey, one of the physicians to the Howard Hospital, has been elected Lecturer on Gynecological Electro-Therapies, and Dr. Lewis H. Adler Lecturer on Diseases of the Rectum.

Through the recent election of Professor J. M. Baldy, the valuable special field of the Gynecean Hospital has been made available to physician pupils who attend "The Polyclinic." The addition of the above lecturers as an auxiliary to the twenty members of the faculty will make the entire course of instruction cover 150 hours every week, from which may be selected the portion desired by each physician pupil.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION will hold its seventeenth annual session at St. Louis, Wednesday, Thursday and Friday, October 14, 15 and 16, 1891. Re-Union dates and an excellent programme will bring out a large attendance. The medical profession is respectfully invited. The officers are as follows: C. H. Hughes, M.D., President, 500 N. Jefferson Ave., St. Louis; E. S. McKee, M.D., Secretary, 57 W. Seventh St., Cincinnati, O.; I. N. Love, M.D., Chairman Committee of Arrangements, 304 N. Grand Ave., St. Louis, Mo.

THE ASSOCIATION OF MILITARY SURGEONS, WISCONSIN NATIONAL GUARD.—The regular meeting of the Association of Military Surgeons of the Wisconsin National

Guard will be held in Milwaukee, June 20, 1891. The proposed meeting of the Surgeons of the National Guard of the United States, which was to have been held in Chicago next July, has been postponed until September, 1891. At that time every effort will be made to organize an Association of Military Surgeons of the National Guard.

About four hundred throughout the United States have more than expressed a willingness to attend. Judging from the correspondence so far, the future of the Association will be very bright, and promises to be of much profit and interest to every one.

At its first meeting papers will be read by Surgeon General Bryant, New York National Guard; Surgeon General Yandell, Kentucky National Guard; Surgeon General Senn, Wisconsin National Guard; Surgeon General of Illinois National Guard.

The Association will be entertained in Chicago by the local Guard. (Signed)

SURG. GEN. SENN, W. N. G.,

Pres. Ass'n. Mil. Surg., W. N. G.

ASST. SURG. RUSH CHANDLER, W. N. G.,

Sec'y Ass'n. Mil. Surg., W. N. G.

135 Grand Ave., Milwaukee, Wis.

WHEREAS, Dr. Chas. G. Bacon, of Fulton, N. Y., aged 75 years, and whose connection with the Oswego County Medical Society the records show to have been since the year 1841; and

WHEREAS, the proceedings of this Society show his continued presence and participation each and every year for the past fifty years without a break or excuse;

WHEREAS, He has occupied every office in the gift of this Society, for most of the time being its financial banker and treasurer; therefore, be it,

Resolved, That we round out the semi-centennial of Dr. C. G. Bacon, and declare him most cordially and unanimously elected our Presiding officer for the ensuing year; and

Resolved, That the Secretary be authorized to send a copy of the above to the *Medical Record*, and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION as a direct challenge to any County or State Society to beat this record.

Official List of Changes in the Stations and Dates of Officers Serving in the Medical Department, U. S. Army, from June 13, 1891, to June 19, 1891.

Capt. Blair D. Taylor, Asst. Surgeon, is granted leave of absence for one month, to take effect on or about the 14th prox. Par. 3, S. O. 146, Dept. of the Missouri, June 13, 1891.

Lieut. Col. Joseph C. Baldy, Asst. Medical Surgeon, is granted leave of absence for two months, on surgeon's certificate of disability, with permission to leave the Dept. of Texas, and authority to enter the Army and Navy General Hospital, Hot Springs, Ark., for treatment therein for a period of one month. By direction of the Acting Secretary of War. Par. 12, S. O. 133, Washington, June 12, 1891.

Lieut. Col. James C. McKee, Surgeon, having been found incapacitated for active service on account of disability incident to the service, is, by direction of the President, retired from active service this date, under the provisions of section 1251, R. S. Par. 4, S. O. 147, A. G. O., June 16, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending June 20, 1891.

Surgeon M. J. Ruth, detached from U. S. S. "Newark" and granted leave of absence for six months, with permission to leave the United States.

Surgeon George A. Bright, ordered to the U. S. S. "Newark."

Asst. Surgeon M. R. Pugh, ordered to the U. S. S. receiving ship "Independence."

Surgeon Howard Wells, detached from Naval Hospital, Chelsea, and wait orders.

P. A. Surgeon J. M. Steele, ordered to Naval Hospital, Chelsea, Mass.

CORRIGENDA.

IN THE JOURNAL of June 14, page 885, second column, the footnotes were transposed, 4 should be 3 and 3 should be 4. On page 884 paragraph 7, line 9, the words windward and lee were transposed.

In same Journal on page 811 for John Erety Shoemaker, read George Erety Shoemaker.
